APPENDIX 1 THEORY

GENERAL SOLUTION OF THE WAVE EQUATION IN AN AXIALLY SYMMETRIC CO-ORDINATE SYSTEM.

Consider a disturbance propagated in an elastic medium. If r, z and χ are the cylindrical co-ordinates, the z-axis vertically downward through the origin, and u and w are the displacements in the r and z directions, the resulting equations of motion will be independent of χ for an axially symmetric system.

Consider a compressional point source (i.e. SH waves will not be considered in the analysis. SV waves may be generated at interfaces in the medium.)

Defining a scalar potential ϕ and a vector potential ψ as follows:

$$u = \frac{3r}{3} + \frac{3r}{3}z$$

and

$$w = \frac{\partial z}{\partial \phi} + 1/r \frac{\partial r}{\partial r} \left(-r \frac{\partial \psi}{\partial r} \right)$$

The equations of motion are satisfied if ϕ and ψ are the solutions of the wave equations

$$\nabla^2 \phi = 1/\alpha^2 \frac{\partial^2 \phi}{\partial t^2}$$
 A1

and

$$\nabla^2 = \frac{1}{\rho^2} \frac{\partial^2 \psi}{\partial t^2}$$

where $\alpha = \sqrt{(\lambda + 2\mu)}$: the compressional wave velocity

and $P = \sqrt{(u/\rho)}$: the shear wave velocity.

 λ and μ are Lames constants, while ℓ is the density of the homogeneous medium. Only the potential $\phi(z,r,t)$ will be considered. The final required solutions to the wave equations A1 are in fact identical in form, although the intervening theory is slightly different. (see BERRY and WEST 1966)

 ϕ (z, r, t) is defined in the time interval (- \propto , \sim).

Taking Fourier Transforms with respect to t

$$\overline{\phi}(z,r,w) = \int_{-\infty}^{\infty} \phi(z,r,t)e^{iwt} dt$$

$$\phi(z,r,t) = \int_{-\infty}^{\infty} \overline{\phi}(z,r,w)e^{-iwt} dw$$
A2

By substituting A2 into A1, it can be seen that $\overline{\psi}(z,r,w)$ satisfies

$$\nabla^2 \Phi = -k_o^2 \Phi$$

the time independent wave equation

where
$$k_{\alpha} = w/_{\alpha}$$

Now r is defined from o to $+\infty$?

Taking the Fourier-Bessel Transform with respect to r.

$$\overline{\frac{1}{2}}(z,k,w) = \int_{0}^{\infty} \overline{\frac{1}{2}}(z,r,w) J_{n}(kr)r dr$$

$$\overline{\oint} (z,r,w) = \int_{\Omega}^{\infty} \overline{\overline{\oint}} (z,k,w) J_n(kr)k dk.$$
 A4

(In an axially symmetric system n = o).

Substituting A4 into A3

$$\left(\frac{\partial^{2}}{\partial r^{2}} + \frac{1}{r} \frac{\partial}{\partial r} + \frac{\partial^{2}}{\partial z^{2}}\right) \left(\int_{0}^{\infty} \frac{1}{\Phi} (z, k, w) J_{o}(kr) k dk\right)$$

$$= -k_{rr}^{2} \int_{0}^{\infty} \frac{1}{\Phi} (z, k, w) J_{o}(kr) k dk.$$
Hence since
$$\frac{\partial^{2}}{\partial r} (kr) + \frac{1}{r} \frac{\partial}{\partial r} J_{o}(kr) = -k^{2} J_{o}(kr)$$

$$\frac{\partial^2 \overline{\Phi}}{\partial z^2} + (k_{\gamma}^2 - k^2) \overline{\Phi} = 0$$

Hence
$$\overline{\phi} = A(w,k) \exp\left[\pm i(k_{\gamma}^2 - k^2)^{\frac{1}{2}} z\right]$$

Therefore

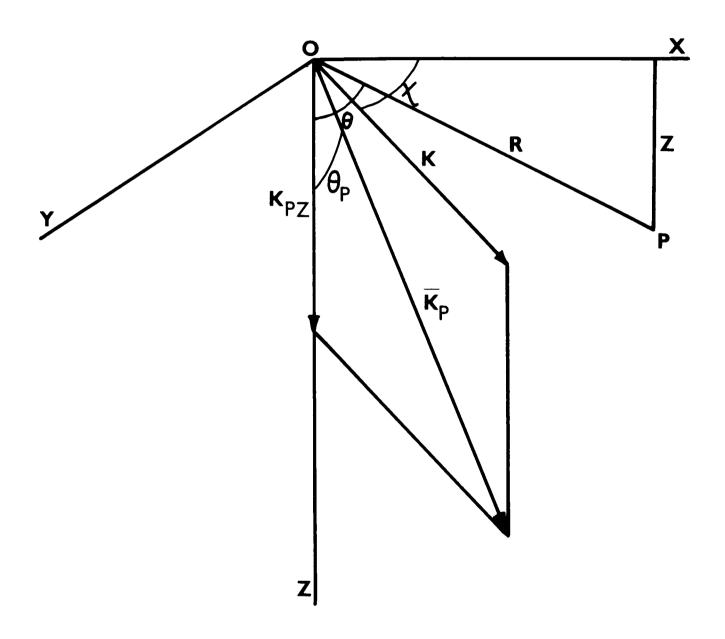

$$\oint_C (z, r, w) = \int_C A(w, k) \exp(\pm ik az) \int_0 (kr)kdk$$
where $a = (k^2 - k^2)^{\frac{1}{2}}/k^2$

Since r is the radial co-ordinate k may be visualized as the radial component of the vector wave number \underline{k}_{n} (Fig. 53 from BERRY and WEST 1966).

i.e.
$$a = \frac{k}{k\alpha}$$
$$= \cos \theta$$

A5 is the general solution of the wave equation for an axially symmetric system.

Fig. 53. Coordinates of the field point P and wave vector $\mathbf{k}_{\mathbf{p}}$.

INTERPRETATION OF THE GENERAL SOLUTION.

The integral representation of $J_n(x)$

$$J_{n}(x) = \frac{x^{n}}{2^{n-1} \left[\frac{1}{2} \right] \left[(n+\frac{1}{2}) \right]_{0}^{\pi/2} \cos(x \cos\theta) \sin^{2n}\theta \ d\theta}$$

For n = 0

$$J_{o}(x) = \frac{2}{7} \int_{0}^{\pi/2} \cos(x \cos \theta) d\theta$$

or since
$$\int_{0}^{2\pi} \sin(x\cos\theta) d\theta = 0$$

$$J_{o}(x) = \frac{1}{2\pi} \int_{0}^{2\pi} e^{ix\cos\theta} d\theta$$

Hence A5 may be written as

$$(z, r, w) = \frac{1}{2\pi} \int_{0}^{\infty} \int_{0}^{2\pi} A(w, k) \exp i(kr\cos\chi^{1} + k\alpha az)kd\chi^{1}dk$$

$$\phi_{1} = A(w, k) \exp i(kr\cos\chi^{1} + k\alpha z\cos\theta) \qquad A6$$

when $\sqrt{1}=0$ \emptyset is the potential due to a plane wave travelling in the x-z plane. Therefore A6 may be considered to be the contribution to the potential at a point P in the x-z plane, due to a plane wave with wave vector $\underline{\mathbf{k}}_{0}$ (Fig. 53).

THE SOURCE.

Assume a compressional point source. A difficulty arises if plane-layered media are to be considered in that the symmetry of the source and media are different. It is necessary to expand the initial spherical waves into a plane wave formulation.

Consider a source acting in a finite domain situated at the origin. Firstly the disturbance must vanish at infinity. Secondly no energy may be radiated from infinity into the region of the source.

A solution of the wave equation A3 satisfying these conditions is

$$\overline{\Phi} = V_0(w) \frac{e^{-ik}o^R}{R}$$

In cartesian wave-vector space

$$\frac{1}{10} = \frac{iV_0(w)}{2\pi} \iint_{\mathbb{R}^2} e^{i(k} \alpha_x^x + k \alpha_y^y \pm k \alpha_z^z) \frac{dk_{0x} dk_{0y}}{k_{0z}} A7$$
(BATH 1968)

Now $k_{\alpha x} = k_{\alpha} \sin \theta_{\alpha} \cos \chi^{1}$ $k_{\alpha y} = k_{\alpha} \sin \theta_{\alpha} \sin \chi^{1}$ $k_{\alpha z} = k_{\alpha} \cos \theta_{\alpha}$

Integration with respect to χ^{-1} is between 0 and 2π

Since, if 1)
$$k_{ox} = k_{oy} = 0$$

$$k_{oz} = k_{o}$$
and 2) k_{ox} or $k_{oy} = \pm \infty$

$$k_{oz} = i \infty$$
Then, because $\cos \theta_{\alpha} = \frac{k_{oz}}{k_{\alpha}}$

$$\theta_{c'}$$
 will vary from $\theta_{c'} = 0$

$$to \qquad \theta_{c'} = \pi/2 - i < 0$$

Choosing the path of integration from 0 to $\pi/_2$ - along the real θ_{α} axis and then from $\pi/_2$ - to -i ∞ (see BATH 1968), A7 may be written

$$\oint_{0} = \frac{V_{0}(w) i k}{2 \pi} \sigma \int_{0}^{\pi/2^{-1}} \int_{0}^{2\pi} e^{i(k_{0x} x + k_{0y} y + k_{0z} z)} \sin \theta_{n} \delta \theta_{n} \delta \chi'$$
A8

Thus in addition to the waves propagated in all directions, there will also be waves corresponding to complex values of θ_{α} . These waves propagate in the x-y plane with a wavelength tending to zero and simultaneously attenuating in the z- direction.

Introducing polar coordinates in the x-y plane

$$x = r \cos 5$$

 $y = r \sin 5$

Then since

$$\sin \theta_{\alpha} d\theta_{\alpha} = \frac{kdk}{k_{\alpha}^2}$$

and
$$\frac{1}{2\pi} \int_{0}^{2\pi} e^{-ikr \cos(\chi^{1} - 5)} d\chi^{1}$$

= $\frac{1}{2\pi} \int_{0}^{2\pi} e^{-ikr \cos(\chi^{1} - 5)} d(\chi^{1} - 5)$

Since the integration is over all wave numbers k_{α} for a given direction \leq

$$\overline{\oint}_{0} = \int_{0}^{\infty} \frac{V_{o}(w) J_{o}(kr) ke^{\frac{+ik}{n}az}}{(-ik_{o}a)} dk$$

This represents the potential due to a point source provided that wavelengths are small compared with the distance to the nearest boundary (EWING et al 1957).

A SINGLE INTERFACE.

Assume two semi-infinite media in welded contact, the plane of intersection being at a depth h below the origin (or source). Let the upper medium parameters be α_1 , β_1 , β_1 , and the lower medium parameters be α_2 , α_2 , α_2 . Imposing the conditions that since the disturbance acts in a finite domain, it must vanish at infinity, and also that no energy may be radiated from infinity into the region of the source.

For $z \le h$

$$\oint_{0}^{\infty} 1 = \int_{0}^{\infty} V_{0}(w)(-i k_{0_{1}} a_{1})^{-1} \exp(i k_{0_{1}} a_{1} |z|) k J_{0}(kr)dk$$

$$+ \int_{0}^{\infty} G_{1}(w, k) \exp(-i k_{0_{1}} a_{1} |z|) J_{0}(kr)kdk$$

For z > h

$$\oint_{\mathbf{2}} = \int_{0}^{\infty} G_{2}(w,k) \exp(i k \gamma_{2} a_{2}z) J_{0}(kr)kdk$$
A9

where $\overline{\psi}_1$ and $\overline{\psi}_2$ are the displacement potentials in the two media. G_1 and G_2 are obtained by imposing the boundary conditions, continuity of displacement and stress, at the interface. These necessarily imply introduction of the potentials $\overline{\psi}_1$ and $\overline{\psi}_2$, as the

boundary conditions for two solid elastic media are dependent on both \oint and ψ . On inserting the expressions for \oint and ψ into the boundary condition equations, a system of four linear equations is obtained for the functions

$$\widehat{G}_1 = G_1 \exp(-i k_{\alpha_1} a_1 h)$$

$$\widehat{G}_2 = G_2 \exp(i k_{\alpha_2} a_2 h)$$

and the equivalent two $\overline{\psi}$ displacement coefficients.

We may write

$$G_1 = R_{p_1 p_1} \left\{ \frac{V_0(w)}{(-i k_{\alpha_1} a_1)} \exp(i k_{\alpha_1} a_1 h) \right\} \exp(i k_{\alpha_1} a_1 h)$$

and
$$G_2 = T_{p_1 p_2} \left\{ \frac{V_0(w)}{(-i k_{\alpha_1} a_1)} \exp(i k_{\alpha_1} a_1^h) \right\} \exp(-i k_{\alpha_2} a_2^h)$$

Thus for $z \ge 0$

$$\overline{\Psi}_{1} = \int_{0}^{\infty} \frac{V_{o}(w)}{(-i k_{o_{1}} a_{1})} \exp(i k_{o_{1}} az) J_{o}(kr)kdk$$

$$+ \int_{0}^{\infty} \frac{V_{o}(w)}{(-i k_{\alpha_{1}} a_{1})} \left[R_{p_{1}p_{1}} \exp i \left[k_{\alpha_{1}} a_{1}^{h+k} \alpha_{1} a_{1}^{(h-z)} \right] J_{o}(kr) k dk \right]$$

and
$$\overline{\Phi}_2 = \int_0^\infty \frac{V_o(w)}{(-i k_{\gamma_1} a_1)} \left[T_{p_1 p_2} \right] \exp i \left[k_{\gamma_1} a_1 h - k_{\gamma_2} a_2 (h-z) \right] J_o(kr) k dk$$
A10

The first term in equation A10 represents the direct compressional wave. The other terms (including also those in the $\overline{\psi}$ potentials) represent waves generated in the two media by the

interaction of the direct wave with the interface.

If the integrands in A10 are interpreted as in the INTERPRETATION OF THE GENERAL SOLUTION, firstly it is seen that R and T are the reflection and transmission coefficients for plane waves. They are functions of k, the density of the two media and the compressional (and shear) wave velocities in the two media. Secondly, the individual intergrals in equation A10 represent the displacement potentials due to all waves travelling from the source to the receiver, not only the ray following the least time path, but also headwaves and rays following non-least-time paths. For example the displacement potential, ψ would be due to all waves travelling from a source in medium 1 as a compresional wave, incident on the interface, and subsequently radiated from the interface as an S wave.

N-LAYERED HALF SPACE.

From equation AlO, it can be seen that at the interface, the integrands in the expressions for the transmitted and reflected P-waves, and the incident P wave differ only by a factor which is independent of the source. Thus the terms describing the redected and transmitted waves may be constructed from the terms which describe the incident waves. Each time a wave component is incident on an interface, four new components are generated, and together these five components must completely satisfy the boundary conditions at that interface. If there is more than one boundary the total number of generated waves is infinite. SPENCER (1960) introduced the concept of a 'generalized ray path'. By starting with the source potential, the displacement potential at the receiver may be determined due to a generalized ray path, built up as a system of individual ray components in each layer of a multilayered medium. Each component is specified only by the mode and direction of propagation across adjacent pairs of interfaces. Thus for example, the displacement potential at the receiver, due to

a $P_1P_2P_3P_3S_2P_1$ reflected wave (including all waves which fall into this category) originating from a source in the uppermost layer with focal depth z (see Fig. 54), is given by

$$\Phi = \int_{0}^{\infty} \frac{V_{o}(w)}{r^{2}ik \cdot a_{1}} (T_{P_{1}P_{2}}(k)T_{P_{2}P_{3}}(k)R_{P_{3}P_{3}}(k)T_{P_{3}S_{2}}(k)T_{S_{2}P_{1}}(k))$$

$$\exp i \left(k \cdot a_{1}^{a_{1}(h_{1}-z) + k} a_{2}^{a_{2}h_{2} + k} a_{3}^{a_{3}h_{3} + k} a_{3}^{a_{3}h_{3} + k} a_{3}^{a_{3}h_{3} + k} a_{3}^{a_{3}h_{3} + k} a_{2}^{b_{2}h_{2}}$$

$$+ k \cdot a_{1}^{a_{1}h_{1}} \int_{0}^{0} (kr)kdk$$
All

It is such an equation as All that needs to be evaluated in order to determine the displacement at the surface due to all the waves following a generalized ray path.

It is convenient to transform All by changing the limits of integration and replacing the Bessel Function by Hankel Functions.

$$J_{o}(kr) = \frac{1}{2} [H_{o}^{(1)}(kr) + H_{o}^{(2)}(kr)]$$
A12

Substituting A12 into A11 we obtain the potential as a sum of two integrals In the integral containing $H_0^{(2)}(kr)$ replace k by -k.

$$\overline{\Phi} = \int_{0}^{\infty} f(k)dk - \int_{-\infty}^{0} f^{1}(-k)dk$$
But $H_{0}^{(2)}(-x) = H_{0}^{(2)}(e^{-i\pi}x)$

$$= -H_{0}^{(1)}(x) \qquad (WATSON 1952)$$
and $T(k) = T(-k)$, $P(k) = R(-k)$

$$(BREKHOVSKIKH 1960)$$

Hence in the example All

A13

$$= \frac{1}{2} \int_{-\infty}^{\infty} \frac{V_{o}(w)}{\frac{(-ik \ a_{1})}{\omega}} (T_{P_{1}P_{2}}(k)T_{P_{2}P_{3}}(k)R_{P_{3}P_{3}}(k)T_{P_{3}S_{2}}(k)T_{S_{2}P_{1}}(k))$$

$$= xp \ i \ (k_{\alpha_{1}}^{a_{1}(h-z)} + k_{\alpha_{2}}^{a_{2}h_{2}} + k_{\alpha_{3}}^{a_{3}h_{3}} + k_{\alpha_{3}}^{a_{3}h_{3}} + k_{\alpha_{2}}^{a_{3}h_{3}} + k_{\alpha_{2}}^{b_{2}h_{2}}$$

$$+ k_{\alpha_{1}}^{a_{1}h} H_{o}^{(1)}(kr)kdk$$

In order to solve A13, we assume that

$$k_{r_i} \stackrel{r}{=} \frac{1}{1}$$

i.e. that the distance from the source to the point of observation (and the dimensions of the model) are large compared with the wavelength of the waves contributing to the integral.

In which case the Hankel function in Al3 may be replaced by its asymptotic approximation.

$$H_0^{(1)}(kr) - \frac{2}{\sqrt{kr}} \exp i(kr - \sqrt{4})$$

Let
$$p = k/k_{O_1} = \sin \theta$$

$$dp = \frac{dk}{k_{O_1}}$$

By transferring the origin to the source, with h, the vertical distance from the source to the first boundary (renumbering the layers accordingly if the source is in a different layer from the receiver)

since
$$\frac{k}{n}$$
 = $\frac{\sin \alpha}{\sin \theta}$ = $\frac{\alpha_1}{\sin \theta}$

which shall be defined as V_n

Then we may say (for the case in question)

$$\exp i(k_{\alpha_{1}^{1}}^{a_{1}}^{h_{1}} + k_{\alpha_{2}^{2}}^{a_{2}}^{h_{2}} + k_{\alpha_{3}^{2}}^{a_{3}}^{h_{3}} + k_{\alpha_{3}^{2}}^{a_{3}}^{h_{3}} + k_{\beta_{2}^{2}}^{b_{2}}^{h_{2}}$$

$$+ k_{\alpha_{1}^{1}}^{a_{1}}^{(h_{1} + z)}$$

$$= \exp i k_{\alpha_{1}^{2}} \sum_{i=1}^{6} \frac{h_{i}(1-p^{2}V_{i}^{2})^{\frac{1}{2}}}{V_{i}}$$

where

$$i = 1, 2, 3 i = 4 i = 5 i = 6$$

$$V_{j} = \alpha_{j}/\alpha_{1} \alpha_{3}/\alpha_{1} \beta_{2}/\alpha_{1} 1$$

$$h_{j} = h_{j} h_{3} h_{2} h_{1}+z$$

$$\Phi = \frac{1}{2} \int_{-\infty}^{\infty} \frac{V_{0}(w)}{(-ik_{\alpha_{1}}a_{1})} (T(p)F(p)^{j}expik_{\alpha_{1}}) \int_{-\infty}^{6} \frac{h_{i}(1-p^{2}V_{i}^{2})^{\frac{1}{2}}}{V_{i}} \sqrt{\frac{2}{\pi^{kr}}}$$

$$expi(kr - \pi/4)k_{\alpha_{1}}^{2}pdp$$

$$= V_{0}(w) e^{i\pi/4} \sqrt{\frac{k_{1}}{2\pi r}} \int_{-\infty}^{\infty} T(p)F(p) expik_{\alpha_{1}} \left\{ \sum_{i=1}^{6} h_{i} \frac{(1-p^{2}V_{i}^{2})^{\frac{1}{2}}}{V_{i}} + pr \right\}$$

$$\left(\frac{p^{2}V_{i}^{\frac{1}{2}}}{1-p^{2}} \right) dp$$
Al4

Al4 may be evaluated at distances from the source which are large compared to the wavelength by the method of steepest descent. The integral is evaluated in such a way that only those waves travelling in the direction of the geometrical ray path contribute substantially to the integral. Al4 may be represented as

$$I = \int_{\mathbf{C}} \exp[f(\mathbf{p})] \mathbf{F}(\mathbf{p}) d\mathbf{p}$$
 A15

where $\ell = k_{\alpha}$ is large, real and positive. f(p), F(p) are analytic functions of the complex variable p, and C is the path of integration in the complex plane.

This path can be deformed, without changing the value of the integral. Using this fact, we try to select a path such that the entire value of the integral is determined by a comparatively short portion of the path. Then the integrand is replaced by a simpler function which coincides sufficiently closely with the integrand over the essential portion of the path. The behaviour of the function over the remaining portions of the path is of no concern.

Now
$$f(p) = f_1(p) + if_2(p)$$

 $p = x + iy$

The integrand in Al5, containing

$$\exp \left(f_1(p) \, \exp i \left(\, f_2(p) \right. \right.$$

will be large when $f_1(p)$ is large.

If we choose C such that the largest values of $f_1(p)$ are located as close to each other as possible, then an approximate value of the integral can be obtained by carrying out the integration only over the largest values of $f_1(p)$.

$$\frac{\delta f}{\delta x} = \frac{df}{dp} \cdot \frac{\delta p}{\delta x} = \frac{df}{dx} = \frac{\delta f_1}{\delta x} + i \frac{\delta f_2}{\delta x}$$

$$\frac{\delta f}{\delta y} = \frac{df}{dp} \frac{\delta p}{\delta y} = i \frac{df}{dx} = \frac{\delta f_J}{\delta y} + i \frac{\delta f_2}{\delta y}$$

Hence
$$\frac{\delta f_1}{\delta x} = \frac{\delta f_2}{\delta y}$$

$$\frac{\delta f_1}{\delta y} = -\frac{\delta f_2}{\delta x}$$

The Cauchy-Riemann conditions.

We define the path of integration as

1) passing through the stationary (maximum) point of
$$f_1$$
 where $p = p_0$
i.e. $df_1 = \frac{\delta f_1}{\delta x} dx + \frac{\delta f_2}{\delta y} dy = 0$

or where $\frac{\delta f_1}{\delta x} = \frac{\delta f_2}{\delta v} = 0$ for any values of dx, dy.

(The point p represents a saddle point in the space of the complex variable, since the modulus of an analytic function cannot have a local maximum within the region of analyticity of the function).

2) directed along the maximum negative gradiant of f_1 . But the real and imaginary parts of an analytic function have the property that in the space of the complex variable, the lines of most rapid decrease of one part are lines of constant values of the other.

i.e. along the contour C

$$f_2 = constant$$

We wish to determine the point p, which must be known for the evaluation of Al5.

At this point

$$\frac{\mathrm{df}(\mathbf{p})}{\mathrm{dp}}\bigg|_{\mathbf{p} = \mathbf{p}_{\mathbf{0}}} = 0$$

Expanding f(p) about p as

$$f(p) = f(p_0) + (p - p_0)f'(p_0) + \frac{1}{2}(p - p_0)^2 f''(p_0) + \dots$$

$$= f(p_0) + \frac{1}{2}(p - p_0)^2 f''(p_0) + \dots$$
Let $p - p_0 = re^{i} / 1$
and $\frac{1}{2}f''(p_0) = Fe^{i\delta}$

Since f2 is constant along the path of integration

$$I_{m}[f(p) - f(p_{0})] = I_{m} (Rr^{2} e^{i(2\gamma' + \delta)})$$

$$= 0$$
i. e. $\sin(2\gamma + \delta) = 0$
or $\gamma = -\frac{\delta}{2} + \frac{n\gamma}{2}$
Al6 (n integer)

is defined as the direction the path of integration makes with the positive x-axis in the vicinity of the saddle point.

But Al6 defines two lines at right angles (4 values of differing by $\pi/2$).

The path of the steepest descent is such that the second derivative of $f(p)_{p=p_0}$ is real and negative (real, since along the path, f_2 is constant).

Hence $(p - p_0)^2 f''(p_0)$ is also real and negative along the path. Hence from a similar analysis to that leading to Al6, we find that n = 2k + 1 (k integer) defining one line (in two directions differing by π).

Let
$$\chi^2 = -\frac{1}{2}(p - p_0)^2 f''(p_0)$$

$$= \frac{1}{2} |r^2 e^{2i} / f''(p_0)|$$

$$= \frac{1}{2} r^2 |f''(p_0)| \qquad \text{since } |e^{2i} / | = 1$$
i. e.
$$= \frac{\pm \frac{r}{\sqrt{2}}}{\sqrt{2}} |f''(p_0)|^{\frac{1}{2}}$$

and
$$\frac{dx}{dp} = \pm \frac{e^{i}}{\sqrt{2}} \left| f''(p_0) \right|^{\frac{1}{2}}$$

Hence we may write equation A15

$$I = e^{\int f(p_0)} \int_C e^{-\int_{\infty}^{p} f(p)} \frac{dp}{dx} dx$$

Assuming F(p) is a slowly varying function in the region of interest, and taking only the first term in the series expansion

$$1 = e^{(f(p_0) + f(p_0))} \sqrt{(2)} e^{i} / |f''(p_0)|^{-\frac{1}{2}} \int_C e^{-(2)^2} d\chi$$

C extends from - ∞ to ∞

but
$$\int_{-\infty}^{\infty} \frac{2}{d\chi} = \sqrt{(\pi/\ell)}$$

$$I = \frac{F(p_0) \sqrt{(2\pi)}e^{i\gamma} e^{i\gamma} e^{i\gamma}$$

In the present case, equation Al4, since $\delta = \arg f''(p_0)$ and $f''(p_0)$ is real and negative and equal to $ig''(p_0)$

$$\delta = -\pi/2, 3\pi/2$$

Thus $\gamma = -\pi/4$, $3\pi/4$ in the neighbourhood of p_o. As long as the contour of integration can be deformed to pass through the saddle point p_o, defined by $f'(p_o) = 0$, along the path of steepest descent, inclined at an angle $-\pi/4$ to the Real p axis, equation Al4 may be evaluated to give (from Al7)

$$\overline{\bigoplus} = V_{o}(w) e^{i\pi/4} \sqrt{\frac{k_{\alpha_{1}}}{2\pi r}} / T(p_{o})R(p_{o}) / \frac{p_{o}}{(1-p_{o}^{2})} \sqrt{2\pi} e^{-i\pi/4}$$

$$\begin{split} \exp k_{\alpha_1} & \left[\begin{array}{c} i \sum_{j=1}^{6} & \frac{h_j (1 - p_o^2 \, V_j^2)^{\frac{1}{2}}}{V_j} + p_o r \right] \\ & \left(k_{\alpha_1} \middle| -i \sum_{j=1}^{6} & \frac{h_j V_j p_o (1 - p_o^2 \, V_j^2)^{-3/2}}{p_o} \middle| \right)^{\frac{1}{2}} \\ & = V_o(w) \left\lceil T(p_o) R(p_o) \right\rceil \left[\frac{p_o^2}{(1 - p_o^2)} & \frac{6}{r \sum_{j=1}^{2}} \frac{1}{p_o V_j h_j (1 - p_o^2 \, V_j^2)^{-3/2}} \right]^{\frac{1}{2}} \\ & \exp ik_{\alpha_1} \left(\sum_{j=1}^{6} & \frac{h_j \, (1 - p_o^2 \, V_j^2)^{\frac{1}{2}}}{V_j} + p_o r \right) \\ & \text{where } r = \sum_{j=1}^{6} & h_j p_o V_j (1 - p_o^2 \, V_j^2)^{-\frac{1}{2}} \\ & \text{since } f'(p_o) = 0 \end{split}$$

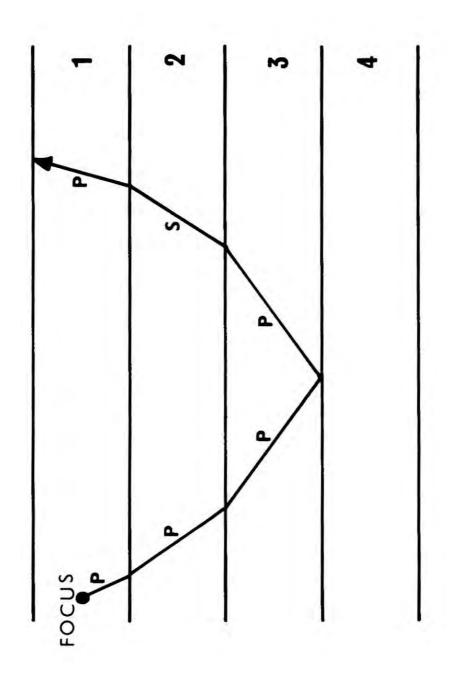

In evaluating Al4 to Al8, no consideration has been taken of poles or branch points. (No account will be taken of the contributions to the integrals by poles, leading to interface and surface waves).

When $p_o < \alpha_1/\gamma_{n+1}$, equation Al8 is the final solution and represents the displacement potential at the receiver due to the geometrical or least time reflection path as in Fig. 54. The explicit expressions for the Reflection and Transmission coefficients may be obtained in a number of references. Consider the reflection coefficients, they contain the radicals

$$(1 - p^2 V_n^2)^{\frac{1}{2}}$$

where $V_n = \gamma_n / \gamma_1$, β_n / α_1 (BERRY and WEST 1966)

Fig. 54. Generalized ray path for a P₁ P₂ P₃ P₃ S₂ P₁ wave originating in the upper layer and being observed in the upper layer of a four layered model.

As a result
$$p = \alpha_1/\alpha_n$$

or $= \alpha_1/\beta_n$

will be branch points, since at each point p, the reflection coefficient can take two values, depending on which sign we choose for the radical. Thus, we have a two sheeted Fiemann surface on each of which sheets the reflection coefficient will be single valued. The sheets will be joined along the branch lines starting at the branch point A_1 , where p = 1/V.

The branch points correspond to the values of p taken for the critically incident reflection when $p = p_c$. When p_o , the saddle point, is less than p_c , as in the evaluation leading to equation A18, that equation is the complete solution. When the angle of incidence is greater than the critical angle, the branch points p_c , will interfere with the contour of integration, and the complete expression for the displacement potential will consist of two parts

$$\emptyset = \emptyset_{REFL} + \emptyset_{HEAD}$$
 A19

where θ_{REFL} is the potential evaluated for the original contour, and the potential evaluated for that part of the contour which must be deformed around the cut, θ_{HEAD} , can be shown to be that due to the critically refracted headwave (EFEKHCVSKIKH, 1960).

The integral around the cut is evaluated as a single integral along the cut from A_1 to ∞ including $\triangle R = R_{OUT} - R_{IN}$. R_{OUT} and R_{IN} are the values of the reflection coefficient on each side of the cut. As in the previous analysis, we again use the method of stepest descent to evaluate the integral. The integration path is deformed in such a way that it goes from the branch point A_1 along the line on which the exponential in the integrand decreases most rapidly. From Al5 this will be the line on which the real part of f(p) decreases most rapidly.

Introducing a new variable q, defined by

$$p = p_C + iq$$

and expanding the exponential in Al5 as

$$f(p_c + iq) = e^{i} f(p_c) + iq e^{i} f(p_c)$$

$$\approx ik_{\alpha_1} g(p_c + iq) = ik_{\alpha_2} g(p_c) - qk_{\alpha_1} g(p_c)$$

Since k_{α_1} is assumed to be large, and we have chosen the path of most rapid decrease, corresponding to the most rapid decrease in the Real part of $f(p) = qg(p_c)$ only small values of q will play an important role in the integrand (BREKHOVSKIKH, 1960).

Again we treat F(p) (see A15) as a slowly varying function in the region of interest.

For small q, the difference in the reflection coefficient on the two sides of the cut can be shown to be related by a constant

$$H = (1 - p_c^2 V_n^2)^{\frac{1}{2}} \int_{p \to p_c}^{r} \frac{R^{OUT}(p) - R^{IN}(p)}{2(1 - p^2 V_{n+1}^2)^{\frac{1}{2}}}$$

where for small q

$$P = 2(-iq)^{\frac{1}{2}}p_c^{\frac{1}{2}}V_{n+1}(1-p_c^2V_n^2)^{\frac{1}{2}}H$$

(BEFFY and WEST 1966)

where
$$V_n = \frac{\alpha}{n} / \frac{\alpha}{1}$$

 $R^{IN}(p)$ is the reflection coefficient as calculated when $p < p_0$ and $R^{OUT}(p)$ is the reflection coefficient when the radical $(1-p^2V_{n+1}^2)^{\frac{1}{2}}$ takes on its negative second value.

(n + 1) is the headwave layer)

The integral around the cut may now be evaluated from 0 to \ll over the variable q.

The integral corresponding to $\widetilde{\bigoplus}_{\mathsf{HEAD}}$ becomes

$$V_{o}(w) e^{i\tau/4} \sqrt{(k_{\alpha_{1}}/2\pi r)} \int_{0}^{\infty} F(p_{c} + iq) exp(k_{\alpha_{1}} f(p_{c} + iq)) idq$$

or

$$\frac{1}{2} = V_0(w) e^{i\pi/4} \sqrt{(k_{\alpha_1}/2\pi r)} \int_0^{\infty} F(p_c) q^{\frac{1}{2}} e^{-(k_{\alpha_1}|f'(p_c)|q)} e^{k_{\alpha_1}f(p_c)} e^{idq} A21$$

where $q^{\frac{1}{2}}$ has been included from the value for $\triangle F$

For large k_{α_1} , A21 becomes

$$\frac{F(p_c)e^{k_{O'_1}}f(p_c)^{\pi^{\frac{1}{2}}}}{\left(2(k_{O'_1}|f'(p_c)|)^3\right)^{\frac{1}{2}}}V_0(w)e^{i\pi/4}\sqrt{(k_{\alpha_1}/2^{\pi}r)}$$

BERRY and WEST 1966

Thus
$$\Phi_{\text{HEAD}}$$

$$= i \frac{V_0(w)}{k_{\alpha_1}} \left[-i \frac{6}{1 - p_c^2 V_j^2} + i \frac{6}{1 - p_c^2 V_j^2} + i \frac{1}{2} \frac{1 - p_c^2 V_j^2}{1 - p_c^2 V_j^2} \right]^{-\frac{1}{2}} \left(\frac{1 - p_c^2 V_j^2}{1 - p_c^2 V_j^2} \right)^{-\frac{1}{2}}$$

where
$$p_c = \alpha_1/\alpha_{n+1}$$
 (n+1 being the 4th layer)

The potentials for both the reflected and headwave terms for ray paths where certain legs are of shear type are identical, but with the relevant values of α and T_p , R_p changed to \mathcal{E} , T_s , R_s

We have that for any ray

$$\overline{\psi} = \overline{\psi}_{REFL} + \overline{\psi}_{HEAD}$$
and
$$\overline{\psi} = \overline{\psi}_{REFL} + \overline{\psi}_{HEAD}$$

depending on whether the final leg of the ray path is a compressional or shear wave.

The REFL terms will be present for all ray paths, but the head wave terms

$$= \overline{\psi}_{CP} + \overline{\psi}_{CS}$$
or
$$= \overline{\psi}_{CP} + \overline{\psi}_{CS}$$

where CP denotes a P headwave and CS denotes an S headwave will only exist if p₀ is greater than the relevant value of α/α_{n+1} , α_1/β_{n+1} .

8 such terms will exist corresponding to the four reflection coefficients and two branch points p_{CP} and p_{CS} .

SURFACE DISPLACEMENTS.

Having determined the displacement potential at the detector, it is necessary to calculate the amplitude of the displacement at the point of observation. Since the synthetic seismogram is to be compared with seismograms recorded on vertical seismometers, the vertical displacement at the surface will be calculated, making use of KNOPOFF'S et al. (1957) coefficients.

Since the absolute intensity of the source is unknown, it is convenient to normalize the amplitude of the initial pulse at unit distance from the source. This amplitude is taken to be unity at a distance h from the source in an isotropic medium having the properties of the first layer.

The displacement amplitude

$$U_{\mathbf{p}} = \nabla \overline{\Phi}$$

The normalizing amplitude is thus

$$\begin{array}{ccc} U_{p_n} & = & \delta \sqrt[3]{SOURCE} \\ \hline \delta r & & r = h \end{array}$$

However, since the assumption that $kr \gg l$ must hold for the final amplitudes, it must also be applied to the normalized amplitude at a distance h from the source

Hence, since
$$\oint_{SOURCE} = \frac{ik_{n_1}r}{r}$$

$$U_{p_n} = \frac{ik_{n_1}Ae^{ik_{n_1}r}}{r}$$

The final amplitude formulae are obtained as $U_p = \nabla_F \overline{\psi}$ where ∇_F is in the direction of the final leg of the ray path. Omitting the phase delay terms corresponding to propagation along the geometrical ray paths

$$Z_{R} = \left[\frac{(1 - p_{o}^{2})\bar{r}\bar{1}}{p_{o}} \right]^{-\frac{1}{2}} \left[T_{P_{1}P_{2}}(p_{o})T_{P_{2}P_{3}}(p_{o})R_{P_{3}P_{3}}(p_{o})T_{P_{3}S_{2}}(p_{o}) \right]$$

$$T_{S_{2}P_{1}}(p_{o})S_{P_{2}}(p_{o})$$

and

$$Z_{C} = \left(\frac{i}{k_{\alpha_{1}} h}\right) \left(\frac{1 - p_{c}^{2} V_{n}^{2}}{1 - p_{c}^{2}}\right)^{\frac{1}{2}} \qquad (\bar{r} \bar{L}^{3})^{-\frac{1}{2}}$$
A22

$$\left[T_{P_{1}P_{2}}^{(p_{c})T}P_{2}P_{3}^{(p_{c})H}P_{3}P_{3}^{(p_{c})H}P_{3}P_{3}^{(p_{c})T}P_{2}^{(p_{c})T}P_{2}^{(p_{c})T}P_{2}^{(p_{c})S}P_{2}^{(p_{c})}\right]$$

where Z_R is the vertical ground displcement caused by a reflected wave and Z_C is that caused by a head wave.

$$\bar{r} = r/h = \sum_{j=1}^{6} \bar{h}_{j} p_{o} V_{j} (1 - p_{o}^{2} V_{j}^{2})^{-\frac{1}{2}}$$

$$\frac{1}{1} = \sum_{j=1}^{6} h_{j} p_{o} V_{j} (1 - p_{o}^{2} V_{j}^{2})^{-3/2}$$

$$\bar{L} = \bar{r} - \sum_{j=1}^{6} h_{j} p_{c} V_{j} (1 - p_{c}^{2} V_{j}^{2})^{-\frac{1}{2}}$$

with
$$h_j = h_j/h$$

(BERRY and WEST 1966)

Identical formulas hold for S-waves incident on the surface, with the appropriate values of α changed to β .

The coefficients S_{p} are the Knoppoff coefficients for incident P waves.

The values of the reflection and transmission coefficients are calculated from the Zoeppritz equations as in RICHTER (1968). The headwave coefficients are calculated from the equation relating H to \triangle R (BERRY and WEST 1966).

DISCUSSION.

The integral equations have been evaluated as symptotically for wave-lengths that are short compared with the dimensions of the model. Using this method the displacement potential at the point of observation is predominantly due to contributions from plane waves following the geometric ray paths from source to receiver. The reflection and transmission coefficients have thus been calculated assuming geometric ray theory. However, since the integrand in equation All is evaluated for a range of values of p about p₀, the saddle point, the F-T coefficients will also vary over that range as they are functions of p. In order to overcome this problem, the F-T coefficients are treated as slowly varying functions of p.

As the point of observation approaches the point at which the front of the headwave merges with the front of the reflected wave, the angle between the reflected ray and the normal to the boundary is close to the angle of total internal reflection. At this point

since $L \rightarrow 0$ in equation (A20).

The formulae thus become inapplicable as the angle of reflection tends to the critical angle. This is because the reflection coefficient is not a slowly varying function of p in this region. On the contrary

$$\frac{dV(p)}{dp} \rightarrow \emptyset$$
 (BP EKOVSKIKH 1960)

CEPVENY (1966) has shown that the amplitude of the reflected wave does not reach its maximum value directly at the critical point (as follows from geometrical ray theory) but beyond it. In this analysis the reflection and transmission coefficients have been considered independent of the frequency of the incident wave. This is not so.

CERVENY (1966) has shown that the maximum amplitude of the reflected waves occurs at increasing distances from the source for decreasing frequencies. The maximum value also decreases with a decrease in frequency.

However, for incident rays with angles below the angle of total internal reflection, geometric ray theory gives relatively exact results, for all frequencies.

No account has been taken of the attenuation of the medium. This will be due to absorption, and loss of energy on diffraction and dispersion from inhomogeneities. Assuming a homogeneous layered medium, the amplitude of the seismic wave will be decreased as

$$A = A_0 E^{-\Omega T}$$

where α is the absorption coefficient and r the distance travelled by the wave. However, for local and regional seismic work α is of the order of 10^{-6} through igneous, metamorphic and dense sedimentary rocks, and hence may be neglected. However, the reflection and transmission coefficients will also be affected by the presence of an absorbing layer. They can be shown to be oscillatory functions of that layer's thickness, d. As d increases the amplitude of the oscillations of the reflection coefficient decreases, until with d sufficiently large, R becomes constant. It is then equal to the reflection coefficient at the upper surface of the layer. In this case no wave is transmitted. (BREKOVSKIKH 1960). However, as stated, absorption is not considered in this analysis.

The integrals have been evaluated assuming a point source, the source potential being converted from that of a spherical wavefront to that of a plane wavefront, with arbitrary time dependence. The amplitude at the point of observation has been calculated in terms of the initial displacement. However, on a real seismic record, the waveform is related to the displacement of the seismometer mass. This will not be identical with the ground displacement, since it will be affected by the seismometer characteristics. However, since the initial disturbance is likely to be highly complex, being associated with an earthquake mechanism, it was considered unnecessary to include the seismometer characteristics in the final amplitude formulae. The errors thus involved, will be negligible compared with the error incorporated in assuming an initial point source.

In the analysis, only a compressional point source is considered. The solutions are not applicable to a shear wave source which will generate SH and SV waves. A compressional source will only generate SV waves on interaction of the wavefront with an interface. However, in the programme, an 'S wave source' has been included by considering a compressional point source generating spherical waves with vectors corresponding to S waves. This facet was included in order primarily to determine the travel time and apparent velocity of the S arrivals.

No account has been taken of the curvature of the earth, or of models other than a homogeneous, horizontally layered system. Thus the final emplitude formulae correspond to an idealized situation. Even with this situation due to the discrepancies involved in using geometric ray theory, the final synthetic seismogram is unlikely to correspond to a real seismogram from the same crustal model. Thus the results should not be equated exactly with records of a real seismogram which is likely to have a highly complex structure, due to inhomogeneities in the crust, small scale velocity fluctuations with depth, attenuation and near surface effects. However, the results will give an estimate of the relative amplitudes (and a direct indication of onset times, and apparent velocities) of the various major arrivals. This will assist identification of the large amplitude arrivals on the real seismic records, which in turn will aid interpretation of those records in terms of crustal thickness, structure and focal depths.

APPENDIX 2

REFLECTION, TRANSMISSION, HEADWAVE and KNOPOFF COEFFICIENTS.

A.2.1. REFLECTION and TRANSMISSION COEFFICIENTS.

Consider plane waves in the vicinity of a plane interface between two homogeneous media, differing both in elastic constants and density.

Consider the 6 waves, corresponding to rays at different angles with the normal to the interface.

	VELOCITY	AMPLITUDE	ANGLE WITH NORMAL	
INCIDENT P	U	Α	a	
INCIDENT S	V	В	b	
REFLECTED P	U	С	c	
REFLECTED S	V	D	đ	
REFRACTED P	Y	E	e	
REFRACTED S	Z	F	f	

The ratio of the density of the second medium to that of the first is K. All angles and velocities conform to Snell's Law.

The theory assumes that all 6 wavefronts represent pure sine waves of the same frequency w.

By applying the two boundary conditions at the interface

- the vector sum of the displacements due to all the waves along the boundary in one medium must equal the corresponding sum in the second medium,
- and 2) the corresponding components of stress must be equalon the two sides of the interface.

we may formulate four equations, the Zoeppritz equations, for an incident P wave and an incident S wave, from which the values of A, B, C, D, E and F may be determined (see RICHTER, 1958).

Now, since the angles of incidence and refraction are related by Snell's Law, when the angle of incidence becomes greater than critical angle, the sine of angle c, d, e or f will become greater than unity. Thus the corresponding cosine becomes imaginary. It is necessary, therefore, that the amplitudes are composed of real and imaginary parts. We may solve the Zoenpritz equations incorporating four real and four imaginary amplitude coefficients by matric inversion.

We have that:-

_							
0	0	0)0	- cos 2b	sin 2a	- cos a	+ sin a
0	$0 K(\overline{V})$	0	0	$\frac{V}{U}$ sin 2b	$\frac{U}{V}\cos 2b$	sin b	- cos b
Ċ	$K(\frac{\mathbf{Z}}{\mathbf{V}})^2 \frac{\mathbf{U}}{\mathbf{Y}}^2 \sin e \sin^2 e \cdot \mathbf{I} = 0$	$-\sqrt{(\sin^2 e - J)}$	U	$-\frac{Y}{U}\cos 2f$	Ú	0	+ sin e
0	2e-1) 0	0	0	$-K_{\overline{U}}^{\overline{Z}}\sin 2f$	$K(\frac{Z}{V})^2 \frac{U}{Z} \cos 2f$	- sin f	- cos f
- cos 2b	sin 2a	- cos a	+ sin a	0	0	0	0
$\frac{V}{U}$ sin 2b	$\frac{U}{V}\cos 2b$	sin b	- cos b	0	0	0	O
$-\frac{Y}{U}\cos 2f$	0	0	+ sin e	0	$-K(\frac{Z}{V})^2 \frac{U}{Y}^2 \sin e \sin^2 e - 1$	$\sqrt{(\sin^2 e^{-1})}$	0
$- K_{\overline{U}}^{\overline{Z}} \sin 2f$	$K(\frac{Z}{V})^2 \frac{U}{Z} \cos 2f$	- sin f	- cos f	0	0	0	0
TI	TH TH	D D	$^{\mathrm{C}}{\mathrm{I}}$	FR	E T	D R	C _R
0	0	0	0	-cos 2b	- sin 2a	+ cos a	+ sin a

where the incident wave is of unit amplitude and the complex coefficients

$$H = H_{P} + i H_{I}$$

A similar matrix form holds for an incident S-wave.

The resultant amplitudes are

$$H = \sqrt{(H_R^2 + H_I^2)}$$

with an associated phase

$$\delta = \arctan H_I/H_R$$

In the present analysis the S velocities have been related to P velocities as

$$\rho = c/1.74$$
 (ANDERSON 1965)

and the P velocities related to the density of the medium, with a three component linear approximation to the Nafe-Drake Curve (NAFE and DRAKE 1959).

For
$$\ell \leq 2.19 \text{ gm/cc}$$

$$\alpha = \frac{1}{0.775} (\ell - 0.42)$$

For
$$2.19 \le (\le 2.81 \text{ gm/cc})$$

 $c = \frac{1}{0.155} ((-1.84))$

For
$$\ell > 2.81 \text{ gm/cc}$$

 $\alpha = \frac{1}{0.335} (\ell - 0.71).$

For waves incident on the free surface, only two resultant reflected waves are produced. The equations for the amplitudes of the resultant P and S waves are as:-

S:
$$\begin{array}{rcl} -C \sin 2d \sin d & + & D \sin c \cos 2d & = & \sin 2b \sin b \\ C \cos 2d & + & 2D \sin d \cos c & = & \cos 2b \end{array}$$

(KOLSKY 1963)

For an incident S wave, cos c becomes imaginary when b becomes greater than $\sin^{-1}\frac{U}{V}$. In this case all the energy will be reflected in the S wave with a resultant phase shift in D, where the phase shift

$$\delta = \arctan\left(\frac{4\sqrt{1 - \frac{1}{\sin^2 a}}\sqrt{\frac{1}{\sin^2 b} - 1}}{\left(2 - \frac{1}{\sin^2 b}\right)^2}\right)$$
(EWING et al 1957)

Graphs have been drawn of the amplitudes and associated phases of the resultant waves from a P and an S wave, incident on the boundary between two elastic media, for all angles of incidence between 0 and 90 degrees. (Fig. 55 - 58) The graphs incorporate both reflection and transmission from a high-low and low-high density interface. It can be seen that the variations of T and R, the reflection and transmission coefficients, are highly complex. The variation in general is sharpest in the vicinity of the critical point, with resultant inaccuracies arising as stated in the evaluation of the intergrals in Appendix A.1.

Graphs have also been drawn of the amplitudes of the resultant waves from a P and S wave incident on the free surface (Fig. 59).

A.2.2. HEADWAVE COEFFICIENTS.

The headwave coefficients are calculated from the equation relating H to ΔR , where F OUT and F in differ by the sign in the radical $(1 - p^2 V_{n+1}^2)^{\frac{1}{2}}$.

If α_1 , α_1 , α_1 , are the parameters of the upper layer and α_2 , α_2 and α_3 the parameters of the lower layer it is found that with $\alpha_4 = \frac{\alpha_2}{2} \frac{1}{1}$ H_{PSP} = $-\frac{\alpha_1}{2} \frac{\alpha_2}{12} \frac{1}{12} \frac{1}{$

$$H_{PSS} = \begin{pmatrix} K_{12} & K_{22} / 2 & (\alpha_1/\beta_2) \end{pmatrix}$$

$$H_{SSP} = (K_{22} K_{12} / 2 (\alpha_1/\beta_2) (\alpha_1/\beta_1)^2$$

$$H_{SSS} = -(K_{22}^2 / 2 (\gamma_1/\beta_2) (\gamma_1/\beta_1)^2$$

$$H_{PPP} = \begin{pmatrix} K_{11}^2 / 2 (\alpha_1/c_2) \end{pmatrix}$$

$$H_{PPS} = \frac{K_{11} K_{21}}{2(\alpha_1/\alpha_2)}$$

$$H_{SPP} = \left(\frac{K_{21} K_{11}}{2} \left(\frac{\alpha_1}{2} \right) \left(\frac{\alpha_1}{2} \right) \right)^2$$

$$H_{SPS} = \sqrt{K_{21}^2 / 2 (\alpha_1/\gamma_2) (\alpha_1/\gamma_1)^2}$$

where HXYZ corresponds to

- a downgoing X wave
- a lateral Y headwave

and an upgoing Z wave from the interface.

 $({}^{\alpha}_{1}/{}^{\beta}_{2}))]/D_{2}$

If
$$A_{11} = (1 - (\alpha_1/\alpha_2)^2)^{\frac{1}{2}}$$
 $B_{11} = (1 - (\beta_1/\alpha_2)^2)^{\frac{1}{2}}$

and $B_{21} = (1 - (\beta_2/\alpha_2)^2)^{\frac{1}{2}}$
 $B_{12} = (1 - (\beta_1/\beta_2)^2)^{\frac{1}{2}}$
 $B_{12} = (1 - (\beta_1/\beta_2)^2)^{\frac{1}{2}}$
 $A_{12} = (1 - (\alpha_1/\beta_2)^2)^{\frac{1}{2}}$
 $A_{22} = (1 - (\alpha_2/\beta_2)^2)^{\frac{1}{2}}$
 $K_{11} = \left[(\{(M_1 - \frac{1}{2}) B_{21}\} / (\alpha_1/\beta_1)) - (\{(M_1 + \beta/2) B_{11}\} / (\alpha_1/\beta_2))\} / D_1 \right]$
 $K_{21} = \left[(\{(M_1 \cdot A_{11}, B_{21}\} / (\alpha_1/\beta_2)) + (\{(M_1 + (\beta_1/\beta_2))\} / (\alpha_2/\beta_2))] / D_1 \right]$
 $K_{12} = \left[(\{(M_2 \cdot A_{22}, B_{12}\} / (\alpha_1/\beta_2)) + (\{(\alpha_2/\beta_2)(M_2 + (\beta_1/\beta_2))\} / ((\alpha_1/\beta_2)) + ((\alpha_1/\beta_2)(M_2 + (\beta_1/\beta_2))) + ((\alpha_1/\beta_2)(M_2 + (\beta_1/\beta_2)(M_2 + (\beta_1/$

$$K_{22} = [(\{M_2 - \frac{1}{2}\} A_{22}) - (\{M_2 + (2/2) A_{12}\}/((2/2))]/D_2]$$

where

if
$$D_{11} = (M_1 + (\rho - 1)/2)^2 / ((\gamma_1/\rho_1)(\gamma_2/\beta_2))$$

$$D_{12} = (\rho A_{11}B_{21})/4((\gamma_1/\rho_1)(\gamma_1/\gamma_2))$$

$$D_{13} = [(M_1 + \rho/2)^2 A_{11}B_{11}]/((\gamma_1/\gamma_2)(\gamma_1/\gamma_2))$$

then
$$D_1 = -(D_{11} + D_{12} + D_{13})^2$$
 and if
$$D_{21} = -((\alpha_2/\beta_2)(M_2 + ((-1)/2)^2)^2)/((\alpha_1/\beta_1))$$

$$D_{22} = -((\alpha_2/\beta_{12})/4(\alpha_1/\beta_2))$$

$$D_{23} = -((M_2 + ((-1)/2)^2)^2 A_{12}B_{12})^2/((\alpha_1/\alpha_2)^2)$$
 then
$$D_2 = -(D_{21} + D_{22} + D_{23})^2$$
 where
$$M_1 = -((\alpha_1/\alpha_2)^2)^2 - -((\alpha_2/\alpha_2)^2)^2$$

from BERFY and WEST (1966)

 $M_2 = (\beta_1/\beta_2)^2 - ($

It can be seen from the values of B $_{21}$, A $_{12}$ and A $_{22}$ that complex coefficients will occur, in which case H $_{XYZ}$ must be divided into its real and imaginary parts.

$$H = H_r + iH_i$$

with resultant amplitude

$$H = |H|$$

and phase shift

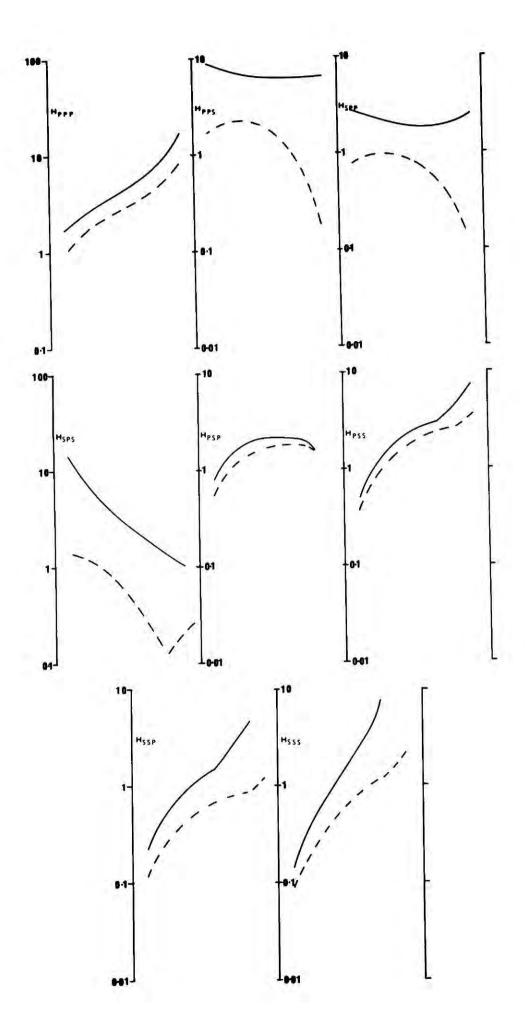

$$\delta = \tan^{-1} \frac{H_{I}}{H_{\Gamma}}$$

Graphs of H_{XYZ} have been drawn for various values of Poisson's ratio for the two media above and below the interface, for a range of values of the P-velocity ratio.

$$H_{PSP}$$
, H_{PPS} , H_{SSP} and H_{SSS} are all complex (Fig. 60)

Fig. 60. Headwave coefficients for a range of values of the P wave velocity ratio (abcissa from 0 to 1), and for two values of the Poisson ratio ratio between the two media on either side of the refracting interface.

represents $\sigma_1:\sigma_2 = 0.15:0.35$ represents $\sigma_1:\sigma_2 = 0.35:0.15$

A.2.3. KNOPOFF COEFFICIENTS.

Consider plane waves incident upon a free surface at any angle, θ , from within an elastic homogeneous half-space. The boundary conditions require that the normal and shear stress vanish at the surface.

For an incident P-wave the vertical component of displacement

$$S_{zp} = \frac{2 \sin \theta}{\cos 2\theta + 2\sin^2 \theta \tan \theta}$$
where
$$\frac{\sin \theta}{\sin \theta} = \alpha/\beta$$

For an incident S-wave

$$S_{zs} = \frac{2 \sin \emptyset \tan 2 \emptyset}{\cos 2 \emptyset \tan \theta + 2 \sin^2 \emptyset \tan \emptyset}$$

In the latter case, when θ is greater than the critical angle, the incident S wave is totally internally reflected and undergoes a phase shift.

If we allow $\boldsymbol{\theta}$ to become imaginary at angles above the critical angle

i.e.
$$\tan \theta \rightarrow i \tan h \theta'$$

we have

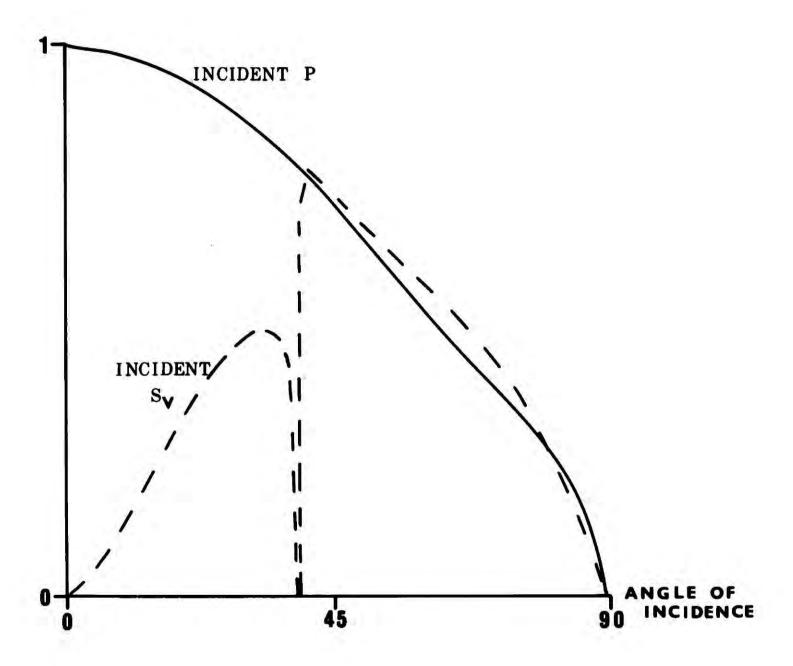

$$\left| S_{zs} \right| = \frac{2 \sin \theta \tan 2 \theta}{(\cos^2 \theta \tan h^2 \theta' + 4 \sin^4 \tan^2 2 \theta)^{\frac{1}{2}}}$$

with an associated phase shift

$$\tilde{o} = \arctan \frac{\tan h\theta' \cos 2\emptyset}{2 \sin^2 \emptyset \tan 2\emptyset}$$

Graphs have been drawn for the vertical component of ground motion for both P and S waves, after normalizing the peak amplitude to unity for vertical incidence, (Fig. 61). The medium is characterized by a Poisson's ratio of 0.25.

P waves.
S waves.

APPENDIX 3

THE PROGRAMME

The programme is written in FORTRAN IV language. It can be run on a 360 IBM computer. One subroutine from the IBM scientific subroutine package is used, SIMQ, for solving a matrix equation.

The programme is divided into two parts

- 1) to compute the amplitude of all required arrivals
- and 2) to convert these numerical results into a synthetic seismogram.
- PART 1 requires 1 data block and output is from the line printer
- PART 2 requires 1 data block plus the output from PART 1, and output is on the IBM 360 plotter.

A.3.1. PART 1.

The problem to be solved is as follows.

- Given 1) the position of a source, S, in an n-layered model
 - 2) the point of observation, O, on the free surface
- 3) the time length of record required calculate the vertical component of ground motion at O, due to every possible ray emerging from S which reaches O within the specified time limit. A further restriction is imposed in discarding those arrivals whose amplitude falls below a specified value

'Every possible ray' includes

- 1) multiply reflected ray paths
- 2) headwaves
- degenerate arrivals i, e. rays that travel from S to O in the same time, but along different ray paths.
- and 4) all possible P-S conversions along the ray path.

No restrictions will be imposed on the position of the source, and the programme will accept a model of up to 20 layers.

(Restrictions arising from the theory in Appendix A1, have to be imposed by the user.)

The programme consists of 1 main and 10 subroutines.

MAIN

Consider an n-layered model with an event originating at focal depth FD.

The layers are numbered from the immediate subsurface, Layer 1, to the lowest layer, Layer NOL.

The layer of focus is calculated layer FL. If the focus lies on a boundary, it is programmed as existing in layer FL, where FL corresponds to the layer number above the boundary. If it exists on the surface FL = 1.

MAIN then generates and calculates the number of ray segments within each layer, for all possible ray paths from the source to receiver.

Since there are an infinite number of arrivals for any model with more than one layer, the ray generation process must be limited in order to be able to use the computer. This is done by calling subroutines which impose the conditions laid down in the formulation of the problem.

Consider a focus in layer FL.

Initially CODE (I), I = 1, FL is set to 1 while CODE (I), I = FL + 1, NOL is set to O

i.e. the direct wave has been generated, since CODE (I) corresponds to the number of ray segments in the Ith layer.

PROCESS A.

By calling the subroutines, the amplitude, phase, apparent ground velocity, and travel time for all possible P, S and P-S conversion rays are calculated.

PROCESS B.

If
$$1 < FL$$
, CODE (1) = CODE (1) + 2

i.e. one reflection from the free surface and the first boundary before the ray arrives at the observation point.

PROCESS A is repeated.

PROCESS B is repeated until the travel time of the multiply reflected ray becomes greater than To + T.

where To is the travel time of the direct P wave and T the time limit imposed in the data.

PROCESS C.

If
$$2 < FL$$
, CODE (1) is set to 1
and CODE (2) = CODE (2) + 2

PROCESS A is repeated.

PROCESS B is repeated until again T > To + T.

PROCESS C is repeated until the maximum number of reflections in layer 2 is reached.

Again CODE (1) is set to 1

CODE (2) is set to 1

while CODE (3) is increased

and the whole process repeated.

In this way, all possible ray paths of multiply reflected rays in

the model are generated.

When the moment comes to generate the next reflection in the layer of focus

CODE (FL) = CODE (FL)
$$+1$$

Since both upward and downward travelling initial rays are allowable.

For reflections in any layer beneath the focal layer

CODE (I)
$$\geq 2$$

No reflections are allowed in the lowest layer since the medium below that layer is not defined.

If the focus originates on the free surface, for the first reflection

CODE (FL) = CODE (FL)
$$+1$$

while for any subsequent reflection

$$CODE(FL) = CODE(FL) + 2$$

The last equation is applied for any increase in the number of reflections in the layer of focus, when the focus is on an intermediate boundary.

Thus on running the main programme all multiply reflected rays are generated with all the required parameters calculated as in process A.

MAIN is then rerun to generate all possible headwaves and their multiple reflections.

A headwave can only exist in any layer beneath the focus. An exactly similar procedure is carried out, as for the multiple reflections with CODE (HEADV/AVE LAYER) = 1.

This time PROCESS A also contains the limitation that the distance travelled in the headwave layer must be greater than a certain value

X where X > O. X > O is applied since $Amp_{HEAD} \longrightarrow \infty$ as $X \longrightarrow O$.

On running through MAIN this second time, all possible headwaves, together with their multiple reflections are generated, with all the required parameters again calculated as in PROCESS A.

The programme then stops.

SUBROUTINE SUMRAY.

This is for computational use only and calculates the total number of ray segments for each ray path for the reflected arrivals.

It also converts CODE(I), I = 1, NOL into RC. For example, if

SUBROUTINE T.D.L.

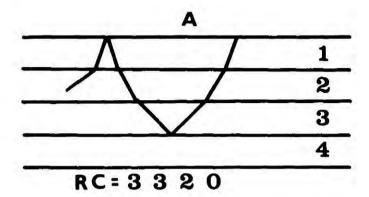

For a single multiply reflected ray path between the source and observation point (i.e. excluding headwaves), this subroutine computes

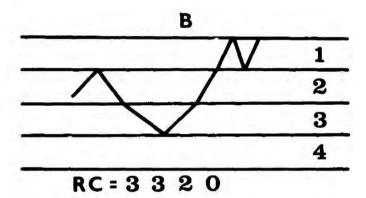

- 1) the type of interaction at each boundary along the ray path T.
- 2) the direction of each ray segment D.
- and 3) the layer numbers of the two layers, involved at each reflection or transmission L1, L2.

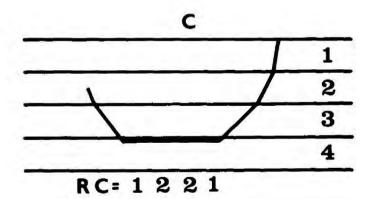

Fig. 62. a) Ray path corresponding to RC = 3320

b) Degenerate ray path for RC = 3320

c) Ray path corresponding to RC = 1221.

$$D = \frac{1}{2}$$
 corresponds to $\begin{cases} \text{an upward travelling ray} \\ \text{a downward travelling ray} \end{cases}$

A single example will be analysed in full. The subroutine in fact can handle any complete ray path, for any focal depth within the model.

Consider the ray path as in Fig. 62a

where the initial data is that

$$RC = 3320$$
 and $FL = 2$.

There are 8 ray segments, therefore there will be 8 values of T, D, L1 and L2.

T (1) must always be set equal to 2.

and L1(2) must always be set equal to FL.

If CODE (FL) is even then the first ray segment must travel downwards.

i.e.
$$D(1) = 2$$
.

If it is odd, then as long as the source is not situated on an interface (which, in fact, has been accounted for in the programme)

$$D(1) = 1$$

Every time the values of T, D, L1 and L2 for a ray segment are determined, the code for the layer L1 is diminished by 1.

Priority is always given to transmission.

In the example we thus have

$$T(1) = 2$$
, $D(1) = 1$, $L1(1) = 2$, $L2(1) = *$ and $RC^1 = 3220$.

(L2(1) is not required in the computation). Since CODE (1) is greater than 1, we can immediately let T(2) = 1 (transmission) and thus

D (2) = 1. L1 (2) and L2 (2) are set equal to 2 and 1 respectively.

Thus we have determined the type of interaction at the first boundary encountered by the ray, and the medium of the incident and resultant rays.

Now
$$RC^{1} = 2220$$
.

The values of all the subsequent T, D, L1 and L2s can thus be determined by an iterative method, imposing the condition that when all the values for T, D, L1 and L2 have been determined,

CODE (I) = 0 for I = 1, NOL.

$$RC^{1}$$
 = 0000 for the case in question.

In the example:-

or

	T	D	L1(incident layer)	L2(resultant layer)
1	2	1	2	*
2	1	1	2	1
3	0	2	1	0
4	1	2	1	2
5	1	2	2	3
6	2	1	3	4
7	1	1	3	2
8	1	1	2	1

(when L2 = 0, the ray is reflected from the free surface).

SUBROUTINE DEG.

Some multiply reflected ray paths between source and receiver will be degenerate. For example, a ray with

$$RC = 3320$$

can travel by two paths from S to O, (Fig. 62a, b) each path having the same travel time, but different resultant amplitudes due to the different

number or reflections of transmissions in each case.

Initially SUBROUTINE TDL defines the path as in Fig. 62 a with the priority on transmission at each interface.

SUBROUTINE DEG starts with the initial values of T, D, L1 and L2 as calculated in SUBROUTINE TDL and then alters each successive type code T = 1 (i.e. transmission) to T = 2 (i.e. reflection), from T(max)to T(1). At each stage the condition is imposed that when the values of T, D, L1 and L2 have been redetermined,

or $RC^1 = 0000$ for the case in question. (see SUBROUTINE TDL).

In the example given this is only true when **T** (2) is changed from a transmission to a reflection.

After such an alteration, the cycle is repeated again, starting with T(max) through to T(change) in this case, T(2). In the example there are no other degenerate arrivals up to this point. T(change-1) through to T(1), when equal to 1, are then successively altered from T=1 to T=2, subject to the restricting condition. Again, after each successful alteration the cycle is repeated starting with T(max) through to T(change). Thus all degenerate arrivals are determined and analysed.

Analysis of reflected refractions is limited to degeneracy 1, (unless the reflections are degenerate), since the output from one or more refractions from the same layer is identical. No allowance has been made for the change in amplitude due to degenerate reflect ed refractions.

SUBROUTINE HEA.

When a ray path has been critically refracted, an extra value of T, D, L1 and L2 has to be included corresponding to the value of each of those parameters for the critically refracted wave. In this case

$$D(HEADWAVE) = O.$$

Thus for a ray path as

$$RC = 1, 2, 2, 1$$

with FL = 2 (the layer of focus) (Fig. 62c)

	T	D	L1	L2
1	2	2	2	*
2	1	2	2	3
3	1	0	3	4
4	1	1	4	3
5	1	1	3	2
6	1	1	2	1

Having calculated the required parameters of this arrival by calling other subroutines, the values of T, D, L1 and L2 are restored to those values for the equivalent reflected wave; in this case

$$RC = 1, 2, 2, 0$$

where	T	D	L1	L2
1	2	2	2	*
2	1	2	2	3
3	2	1	3	4
4	1	1	3	2
5	1	1	2	1

SUBROUTINE PS.

This subroutine calculates all the possible P-S conversions for a specified ray path. Initially the complete ray path is composed of P rays (coding 1). The first ray segment is then converted to an S wave (coding 2), with successive alterations as (for a ray path containing three segments)

111

211

121

221

112

212

122

222

At each stage, the required parameters of the complete ray path are calculated by calling other subroutines.

This subroutine also contains the output commands (SEE COMPUTATIONAL PROCEDURE).

SUBROUTINE ZVANGT.

This subroutine computes for multiply reflected arrivals only,

- 1) the velocity and layer thickness for each part of the ray path.
- 2) the angle of incidence at each interface
- 3) the apparent ground velocity of the arrival
- and 4) the total travel time of that arrival.

It is not possible to calculate the exact ray path between source and receiver directly. However, since

1) the direction of each segment of the ray path is known

- every interaction at each interface (whether transmission or reflection) is known
- and 3) the P or S type of each segment of the ray path is known it is possible by varying the angle of descent or ascent of the initial ray segment from the source to vary the epicentral distance of that complete ray path until it lies within specified limits on either side of the observation point. Once the ray path has been determined, the travel time may be computed.

SUBROUTINE ZVA.

This subroutine performs the same function as ZVANGT, for critically refracted headwaves. In this case, the initial angle of descent is fixed by the critical angle for the headwave. If the observation distance from the source is less than the critical distance for a headwave arrival, the action will be returned to the part of the programme which called this subroutine.

SUBROUTINE AMPHA.

This subroutine calculates the final amplitude and associated phase (arising from reflection and transmission) of the ground motion for a complete ray path.

For each ray incident upon an interface, the following parameters are known and recorded

- 1) the type of incident ray, whether a P or an S wave
- 2) the type of interaction with the interface whether
 - a) reflection
 - b) transmission
 - or c) headwave refraction

- the velocity of the indicent ray medium, and the medium on the opposite side of the interface
- 4) the angle of incidence of the incident ray
- 5) in the case of headwaves, the type of the emanating ray, whether P or S.

thus it is possible to compute (in this case by calling either subroutine ZO or HEAD), the amplitude and phase of the resultant wave at each of the interfaces. The Knoppoff coefficient for the surface displacement is also calculated for the particular angle of incidence and type of the final ray segment.

The final amplitudes are then calculated as in equation A22. The associated phase

 $\delta = \Sigma \delta_i$

where δ_i is the phase change associated with the ith interaction at an interface.

(in fact, if equation A22 is written as

 $z_r = A * (COEFFICIENTS OF INTERACTION)$

 $\Sigma_c = B * (COEFFICIENTS OF INTERACTION)$

Both A and B are 'carried over' to SUBROUTINE AMP from ZVANGT and ZVA respectively.

SUBROUTINE ZO.

This subroutine calculates the reflection and transmission coefficients for a specific ray incident on a boundary, returning the amplitude and phase of the specified resultant ray to AMP. The method used is as described in APPENDIX A. 2. 1.

SUBROUTINE HEAD.

This is equivalent to ZO, but calculates the required headwave coefficients (see Appendix A. 2. 2.).

A. 3. 2. COMPUTATIONAL PROCEDURE.

Fig. 63 represents the main procedure followed. Data is input into the main programme. The number of ray segments in each layer is generated in MAIN.

1) REFLECTIONS AND TRANSMISSIONS.

Consider the point in MAIN where

- 3 segments have been generated in layer 1.
- 3 segments in layer 2.
- 2 segments in layer 3.
- 0 segments in layer 4.

for a four layered model, with the focus in layer 2.

CALL SUMRAY to calculate

RC = 3320

and the total number of ray segments SC = 8.

RETURN TO MAIN.

CALL TDL to calculate T, D, L1 and L2 for all the ray segments.

RETURN TO MAIN.

CALL PS

(POINT 1) All segments are initially P rays (POINT 2) CALL ZVANGT.

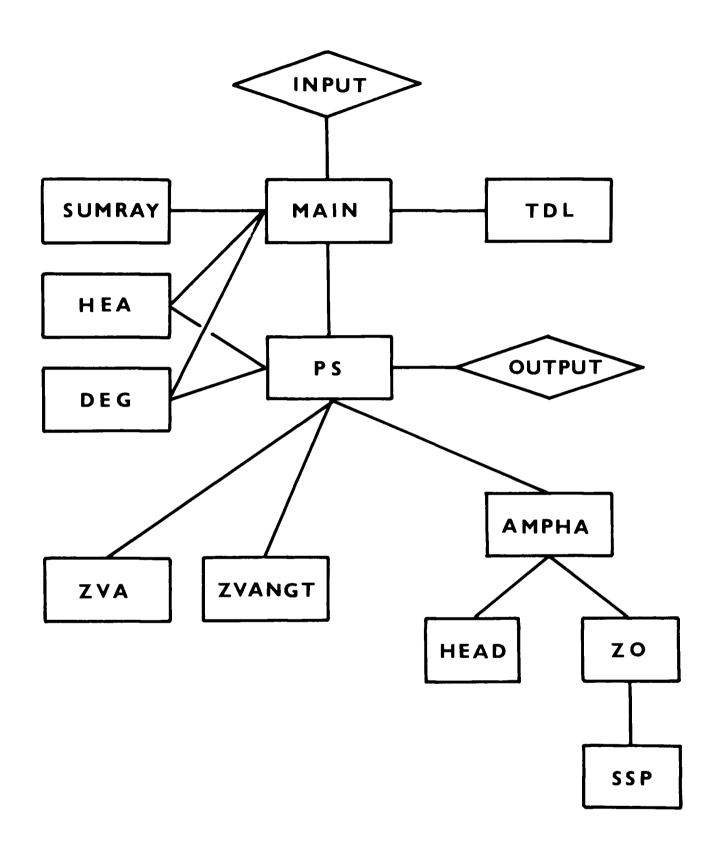

Calculate 1) Velocity

2) Layer thickness

and 3) angle of incidence of each ray segment such that epicentral distance lies within

required limits. Calculate travel time T.

Fig. 63. Computational Procedure for Synthetic Seismogram Programme.

RETURN TO PS.

CALL AMP

Calculate final amplitude and associated phase by calling ZO.

RETURN TO PS

OUTPUT

Change P segments to S segments returning to POINT 2 for each P-S conversion (POINT 3).

RETURN TO MAIN.

CALL DEG

Calculate degenerate ray path T, D, L1 and L2 CALL PS (repeat section from POINT 1 - POINT 3) RETURN TO DEG

If there are no ther degenerate arrivals RETURN TO MAIN

Generate the next ray path.

2) When all reflections have been analysed, the programme is repeated for headwares

ZVANGT being replaced by ZVA

ZO being replaced by HEAD

and HEA included to calculate the extra values of T, D, L1 and L2 corresponding to the headwave segment.

INPUT.

The following parameters are required as data.

- 1) NOL, the number of layers in the model.
- 2) PTS = 0 if all P and S conversions are to be considered.
 - = 1 if only P waves are to be considered.
- 3) MARK = 1 if critical distance of headwaves is to be output.

	= 0	if it is not.
4) IWR	= 0	if output is to include information
		about the model.
	= 1	if output is only to include parameters
		of the various arrivals.
5) ROH	= 0	if both multiply reflected waves and

- 5) ROH = 0 if both multiply reflected waves and headwaves are to be considered.
 - = 1 if only headwaves are to be considered.
 = -1 if only multiply reflected waves are to be considered.
- 6) Z(I), V(I), I = 1 --- NOL.

The layer thicknesses and associated compressional wave velocities of the model.

- 7) FD the focal depth of event.
- 8) AML the amplitude cut off.
- 9) UD the nomedizing distance, h
- 10) XO observation distance.
- 11) DELX limits imposed on XO.
- 12) DELT the length of record required in seconds after the onset of the direct P wave arrival.

OUTPUT.

The initial output contains information about the model, which has been read in as input.

If the focal depth is greater than the sum of the layer thickness 'FOCUS BELOW STRUCTURE'

is printed and the programme terminates.

The required parameters are printed as

RAY NUMBER RAY TIME DISTANCE VELOCITY
AMPLITUDE PHASE DIS. IN. REF. DIRECTION
P-S CODE.

Where

RAY NUMBER : is an integer counting the number

of output ray paths.

RAY : RC giving number of ray segments

in each layer.

TIME : Travel time of RAY.

DISTANCE : Epicentral distance (lying within

XO + DELX).

VELOCITY : Apparent ground velocity of arrival.

AMPLITUDE : Calculated amplitude of arrival.

PHASE : Associated phase of arrival

(in degrees).

DIS. IN. REF. : Distance travelled in refracting

layer for headwave arrival.

DIRECTION : coded direction path D(I), I = 1, SC

(where SC = total number of

ray segments).

P-S CODE : coded P-S type of ray segments in

ray path.

For headwave arrivals, if the distance travelled in the headwave layer is less than a certain distance X, (set equal to 10 units in AMPHA)

'NO HEADWAVE AT CRITICAL DISTANCE'

is printed.

If the observation distance from the source is less than the critical distance from source to receiver, the programme merely proceeds to the next ray path without any output being printed.

If the total path length is less than the normalizing distance

'RAY PATH LESS THAN UNIT DISTANCE'

is printed.

This part of the programme has been completely debugged, and has been shown to work for any horizontally n-layered model (where $n \le 20$) and any focal depth, subject to the limitations discussed in APPENDIX 1.

A. 3.3. PART 2.

The resultant output from PART 1 is a spike function in the time domain, each spike with its associated phase. This function cannot be immediately interpreted in terms of a synthetic seismogram. In order to produce such a result an input function must be altered by a factor depending on the amplitude and phase of each of the resultant 'spikes'.

An exactly similar source function satisfying the radiation condition that

1) the disturbance vanishes at infinity

and 2) no energy is radiated from infinity into the source region, has been assumed for both P and S sources. This has been taken since the wave equation is exactly equivalent to

$$\nabla^2 \overline{\psi} = -\kappa_{\rho}^2 \overline{\psi}$$

where $\overline{\psi}$ is the shear wave potential.

The resultant solutions are identical, except that K_{ℓ} , is replaced by K_{ℓ} , (BERRY and WEST 1966).

However the source function for S-waves is highly unlikely to be equivalent to that for P waves, and the resultant arrivals should only be taken as indicative of the relation between P-wave and S-wave amplitudes.

The interaction coefficients in this analysis are independent of frequency. It can thus be seen that the multiple reflection 'amplitude' is also independent of frequency (Equation A22). The headwave 'amplitudes'

depend on 1/w and have been evaluated in PART 1 assuming unit frequency.

Thus interaction between the spike function and the source function, will depend on the frequency content of the source function since

$$\overline{Z}_{\text{HEAD}} = \underline{Z}_{\text{HEAD}}$$

where $\mathbf{Z}_{\mbox{HEAD}}$ is the calculated headwave amplitude from PART 1.

INPUT FUNCTION.

Consider the function.

F(t) =
$$\frac{1}{5} \left[1 - \cos \delta t + \frac{1}{m^2} (\cos m \delta t - 1) \right]$$

for $0 \le t \le T$.

where
$$F(t) = 0$$
 for $t < 0$

and
$$F(t) = F(T)$$
 for $t > T$

(MUELLER 1967).

$$m = \frac{N+2}{N}$$

and
$$\delta = \frac{N\pi}{3}$$

for N = 1, 2, 3, 4 etc.

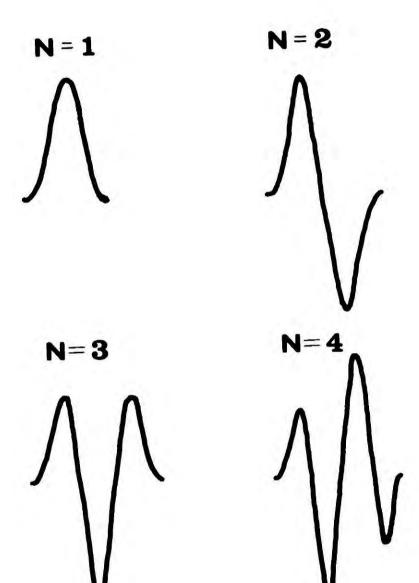

$$F^{1}(t) = \sin \delta t - \frac{1}{m} \sin m \delta t$$

may be said to correspond to an 'input' function of order 1, 2, 3, 4 etc. This function has been plotted as in Fig. 64. In order to obtain a synthetic seismogram, the input function was transformed to obtain the complex Fourier spectrum

with amplitude spectrum A(w) and phase spectrum
$$\phi(w)$$

These two spectra were then altered for each individual spike as

Fig. 64. Input Function for N = 1, 2, 3, 4.

$$A^{1}(w) = A(w) * Z(w)$$
and $\phi^{1}(w) = \phi(w) + \delta(w)$

where Z(w) is the amplitude of the spike and S(w) its associated phase.

As stated, in this analysis only $Z_{\mbox{\scriptsize HEAD}}$ is a function of frequency.

The resultant amplitude and phase spectra were then transformed back into the time domain, to obtain the output waveform for each individual arrival.

The resultant wavelets were summed in the time domain to obtain the final seismogram. The transform method used was the Fast Fourier Transform of COOLEY and TUKEY (1965). This requires that the data consists of 2^N values where N is some positive integer.

The initial wavelet as in Fig. 64, was thus sampled at 32 equally spaced points (i.e. N = 5). A 'time unit' thus corresponded to 0.01 seconds.

This time function was transformed into its Fourier spectrum using the SUBROUTINE NLOGN (ROBINSON 1967). Thus, the frequency spectrum was obtained sampled at frequencies f = j/q cycles per time unit, where q = 32

and
$$j = 0, 1, 2, \dots, q-1$$
.

The associated amplitude and phase spectra were altered for each individual spike and the resultant frequency spectrum transformed into the time domain, again using subroutine NLOGN. The resulting wavelets were summed in the time domain, with a sampling interval equal to the time unit, 0.01 seconds. The amplitude at time $T_{\overline{MIN}}$ + T was then output on the IBM 360 plotter.

 $\boldsymbol{T}_{\mbox{min}}$ is the onset time of the first arrival at the observation point.

t increases from O to $T_{max} + 0.32$ secs. where T_{max} is the onset time of the last calculated arrival.

This procedure was computed as Programme FIS.

INPUT.

N : Number of output arrivals from Part 1.

TIM (I) Onset time

AMP (I) Amplitude

PHA (I) Phase

XH (I) I = 1, N. Distance travelled in refracted layer

of the N arrivals determined from

Part 1.

FIX : If equal to YES

Amplitude scales on graph are input in

CMIN and CMAX.

: If equal to NO

New scales are computed.

X (I), I = 1, 32. The input time function data.

CMIN Maximum and Minimum values of

CMAX Amplitude Scale.

The final amplitudes have been increased by a factor of 10^2 for ease of computation. The programme was run on the IBM 360 NUMAC computer and considerable use was made of scratch files. The commands for running the complete programme are noted after the printout of the programmes.

XC denotes the compiled version of file X

DAT 1 contains the data for PART 2

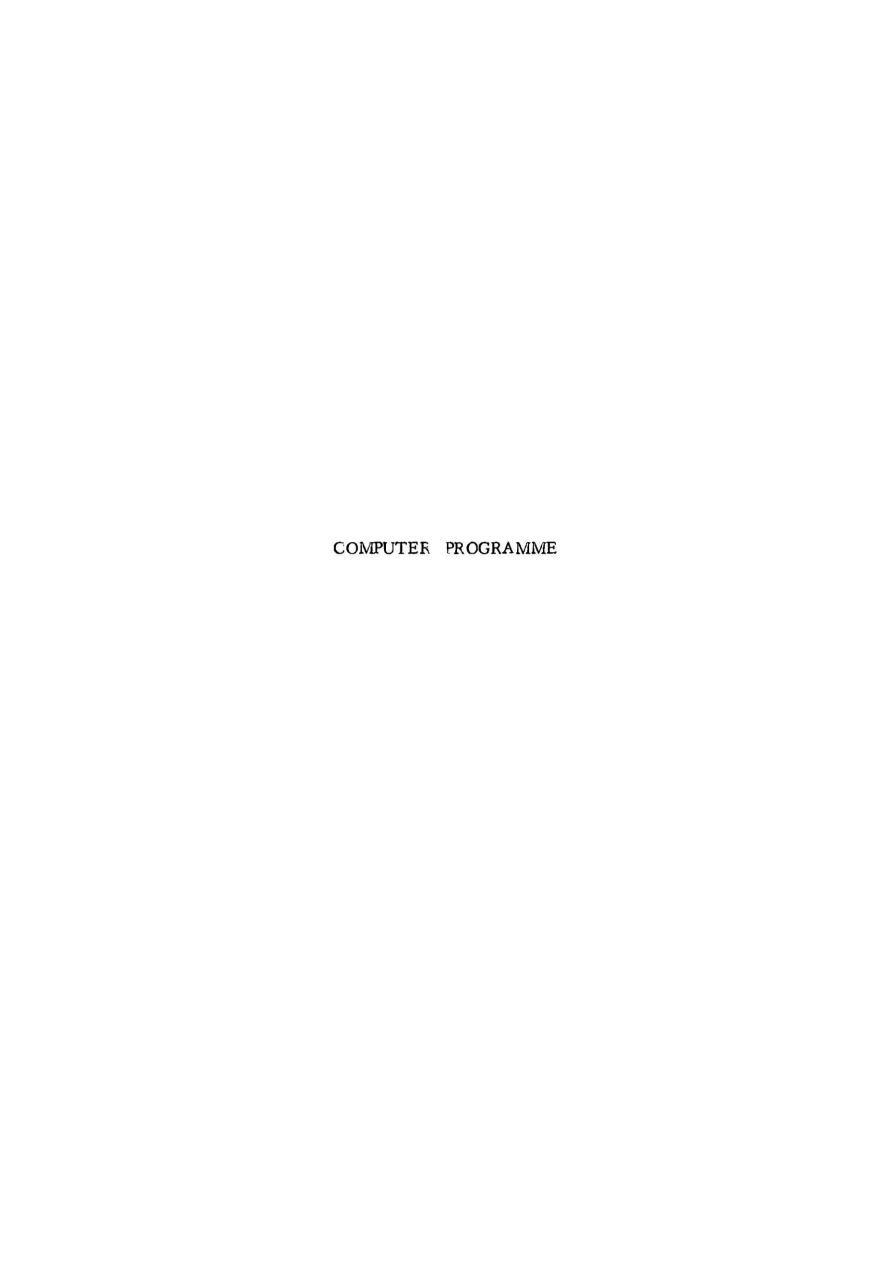

D contains FIX and X (I), I = 1, 32 for part 2.

The programme uses an increasing amount of CPU time

with 1) increasing epicentral distance

and 2) increasing length of record required.

However, 10 second records for an event originating 50 km from the observation point can be computed in approximately 100 seconds. For epicentral distances beyond 200 km, it is necessary to divide the analysis into component parts making use of PTS and ROH in the input.
