## Abstract

This thesis presents the reactivity of dienylboronated compounds towards arylnitroso and carbonylnitroso derivatives and its use in the synthesis of heterocyclic and polycyclics compounds (see graphical abstract).

The first study focused on the reactivity of dienylboronate compounds with arylnitroso derivatives resulting in pyrrole or furan products. The outcome and efficiency of the reaction is related to the boron on the dienyl moiety and the solvent used. Depending on the conditions, pyrroles, boronated MIDA ester oxazines or nitrones could be obtained. A one-pot strategy was then applied to synthesise oxazoline derivatives using nitrones as an intermediate.

Theoretical, as well as experimental, work has supported that the formation of the pyrrole was obtained by a regioselective nitroso Diels-Alder reaction/rearrangement/borate elimination cascade process. Details on the nitrone formation have not been clarified, but further investigations are on-going.

Secondly, attention was focused on the reactivity of dienylboronate compounds with carbonylnitroso derivatives. Contrary to the arylnitroso species, the nature of the carbonylnitroso had a dramatic impact on reactivity. On the one hand, similar reactivity towards the formation of pyrroles and boronated MIDA ester oxazines was observed, however, by employing a higher electron-deficient carbonylnitroso species, the product resulting from a nitroso-ene reaction was obtained.

Ene-product was used as the key intermediate for the synthesis of different polycyclic compounds. A multicomponent, one-pot, Diels-Alder/allylboration procedure was optimised to yield various structures depending on the nature of the dienophile and the aldehyde.

To diversify the chemistry of the ene-product another sequence was designed using the pyrrole synthesis. A multi-step pathway was optimised to afford novel fused bicylic oxazine-pyrrole products.

## Acknowledgements

Firstly, I would like to thank my supervisors Dr Bertrand Carboni and Prof. Andrew Whiting for giving me the opportunity to work on this project. Thanks to their advice, assistance and support through these years, my journey as a PhD student has been very enriching. I know that boron chemistry is one of their areas of preference, but I have to say that even though it was highly stimulating, boron chemistry can be very frustrating as well. I must confess that since I started this project, I now have nightmares every time I'm travelling and staying in a B&B. For 99.99% of the people around the world, B&B means Bed & Breakfast; whereas to me it now means Boron & Boron. Anyway, it's too late for me now; every hero has his curse, and this will be mine.

Like a brave character in an adventure fiction, I travelled miles and miles, through all of France, from my native cosy Alsace to rainy Brittany, in Rennes, where my life as "only" a PhD student started. I met and worked there, with different friendly and helpful people who made my adaptation in this new environment easier. I would like to thank the two lab-partners Dr. Rémy Hemealaere and Dr. Aurelie Macé who allowed me to work in a relaxed and pleasant atmosphere, and our lab neighbour, my favourite Peruvian, Johal Ruiz, with whom I had some really good moments. I'm also grateful to Dr. Francois Carreaux and Dr. Fabienne Berrée who were there for me when I needed them, and to Dr. Fabien Tripoteau, who did substantial preliminary work on the subject and was always available when I contacted him.

After finishing the first half of the journey, I arrived at a turning point, when prompted by my increased audacity, I started to see everything around me bigger; it was time for me to move from Brittany to GREAT Britain. Thus, I crossed the sea to reach a very beautiful city in the North East of England; Durham. Before going, I had only heard rumours and legends about

this place, like people there do not speak English, but Geordie English, for example. It's totally true. So, after some time of adaptation, I succeeded to fit in and really had a nice time with all my colleagues, Dr. Farhana Ferdousi, Dr. Alexander Gehre, Dr. Wade Leu, Dr. Adam Calow, Hesham Raffat Shawky Haffez, Enrico La Cascia, Katrina Madden, David Chisholm, Sergey Arkhipenko, Alba Pujol, John Purdie, and all the students who came to work with us. As I promise, a would like to give a special mention to Dave, ma biche, who helped me to crystallise some of my compounds, and to Enrico and Wade for their support, especially every time we went to The Swan and Three Cygnets and to Fabio's. By working on this interesting project, I also had the opportunity to work in collaboration with Dr. Mark Fox who provided the theoretical DFT calculations within this thesis, and I'm thankful for all these results.

For a journey as a PhD thesis in chemistry to be successful, you need to rely on some other partners. Thus, I would like to thank all the staff involved in the following services; the CRMPO (Centre Régional de Mesures Physiques de l'Ouest), and the NMR department from Rennes University, and also the NMR, the mass and the crystallographic department from Durham University for all their help and expertise.

I'm also grateful to la Région Bretagne and to the Department of Chemistry of Durham University for the funding which allowed me to work on this project.

Cependant je n'oublie pas les personnes qui sont toujours en France, et pour un expatrié, il est toujours bon de rentrer chez soi. Ce prochain paragraphe est dédié aux personnes que malheureusement je n'ai que peu vues durant ces années que ce soit à Orléans ou en Alsace. Petite dédicace à mes deux familles qui m'attendent à bras ouverts à chaque fois que je retrouve mes terres d'origine. Je voudrais premièrement remercier ma famille; mes parents, frère et sœur pour leur soutien durant ce périple. Je voudrais ensuite glisser un mot pour ma famille de substitution, au sein de laquelle je partage de nombreuses amitiés de longues dates. Merci pour les mémorables moments que l'on passe ensemble à chacun de mes retours. Dans de nombreuses années certains murs s'en souviendront encore.

I would like to thank all the other friendly people I was involved with during these three years; my flatmates, basketball mates, and many others I met during social events.

Finally, because nice stories always finish with a happy ending, the last words are for a very special person to me. I'm so glad that we succeeded to cross the polystyrene boarder between our two benches. I came to know you through the months, and I discovered a wonderful and funny person. Mona, thank you for everything, sooooo much.

Now it's time, for the most brave of you, to see what I've done the past years. Good luck and see you for other adventures!!!!!

## I. Introduction

Multicomponent reactions involving catalytic or non-catalytic step(s) have become essential tools in the field of synthetic organic chemistry.<sup>1,2,3,4,5,6,7,8,9</sup> Several of these, which now bear the name of their inventors: Strecker; Hantzsch; Biginelli; Mannich; Passerini or Ugi; have been known and widely used for many years, and the development of new multicomponent processes still receives considerable attention. Indeed, these reactions offer a number of attractive advantages including simple experimental procedures, high convergence, and access to diverse structural and functional systems, often with high levels of atom economy. Boron compounds have long been ignored in this attractive area of research despite their wide range of reactivity.<sup>10,11</sup> In 1993, however, Petasis and co-workers reported a new synthesis of allylamines via stepwise condensation of a secondary amine, para-formaldehyde and (E)styryl boronic acid.<sup>12</sup> This was the first report of this type of transformation, which is now referred as the Petasis borono-Mannich reaction, and was later extended to a wide variety of other aldehydes, such as glyoxylic acid (for example), boronic acids, esters or trifluoroborates and other amine partners.<sup>13,14,15</sup> Subsequently, other multicomponent reactions involving trialkylborane,<sup>16,17</sup> alkenyl-,<sup>18,19</sup> aryl-,<sup>20,21</sup> allyl-,<sup>22</sup> allenyl-,<sup>23</sup> and alkynyl boronic acids or esters<sup>24,25,26</sup> have been reported in the literature. Boron substituted 1,3-dienes and heterodienes have also been successfully used as key elements in such strategies.<sup>27,28</sup>

# II. Boron-substituted 1,3-(hetero)dienes in multicomponent processes

### **II.1** 1-Boron-substituted 1,3-dienes

The first Diels-Alder reaction involving a 1-boron-substituted 1,3-diene was described in 1972 by Mikhailov and co-workers,<sup>29</sup> and it was only fifteen years later that the groups of Vaultier and Hoffmann highlighted the real potential of these compounds in tandem cycloaddition [4+2]/allylboration processes.<sup>30</sup> These dienes reacted with activated dienophiles, such as maleic anhydride **2b** or *N*-phenyl maleimide **2a**, at relatively high temperatures (80 °C in toluene) to afford exclusively the *endo*-isomers **3a-b** (Scheme 1). The resulting cycloadducts, which contain an allylboronate functionality, then reacted with aldehydes to afford the corresponding homoallylic alcohols **5a-b** with high diastereoselectivity (de > 95%).

Scheme 1. 1-Boron-substituted 1,3-diene in a tandem cycloaddition [4+2]/allylboration sequence.

In the case of methyl acrylate or acrylonitrile, a mixture of *endo* and *exo* diastereomers was obtained regioselectively at higher temperature, in a 1:1.6 to 1:1.8 ratio. By contrast, the [4+2] cycloaddition proved to be completely regioselective when performed on the catechol derivative **6** in the absence of solvent.<sup>31</sup> The use of a stoichiometric amount of EtAlCl<sub>2</sub> as

Lewis-acid catalyst provided a lowering of the reaction temperature, a shortening of the reaction time and good stereocontrol (Scheme 2).<sup>32</sup>

Scheme 2. Lewis-acid catalyst in the tandem cycloaddition [4+2]/allylboration sequence.

Alternatively, simple heating of a mixture of a 1-bora-1,3-diene **10**, a dienophile **12** and an aldehyde **11** gave direct access to polysubstituted cyclohexenes **13** that were difficult to prepare using the previously reported two steps methodology.<sup>33</sup> A concise and efficient synthesis of an advanced precursor of Clerodin **14**, a powerful antifeedant natural product, has been reported using a strategy based on this three-component process (Scheme 3).<sup>34</sup>

Scheme 3. Synthesis of an advanced precursor of Clerodin 14.

Extension of this work to the intramolecular version is depicted in Scheme 4. The bicyclic lactone **19** was obtained stereoselectively from a diene-yne **15** in a one-pot process with control of the relative stereochemistry of the five stereogenic centers.<sup>35</sup>

Scheme 4. Intramolecular DA/allylboration sequence.

Concerning the access to enantioenriched compounds by using chiral boron substituents, no diastereoselectivity was observed with the (+)-pinanediol ester **20a** and *N*-phenyl maleimide **2a**.<sup>36</sup> 1,3-Dienyldioazaborecane **20b**, derived from a chiral aminodiol of C<sub>2</sub> symmetry, underwent a faster cycloaddition, as already observed for similar tetra-coordinated boron species,<sup>37,38</sup> but giving only a modest 2.2:1 ratio of diastereisomers. By contrast, the cycloadduct **24** was obtained as a single product with excellent stereoselectivity in 84% yield, however, this could probably be attributed to the special structure of the dienophile **23** used (Scheme 5).<sup>39</sup>

Scheme 5. Diastereoselective DA reaction with N-phenyl maleimide 2a and 4-phenyltriazoline-3,5-dione 23.

Finally, interesting results were reported with methyl acrylate **12** and dienes derived from tartrate esters **25** (9/1 de, 70% ee for the major isomer) (Scheme 6).<sup>40</sup>

**Scheme 6.** Asymmetric synthesis of a  $\alpha$ -hydroxyalkyl cyclohexane.

In 2003, Hall and co-workers reported the application of electron-rich alkoxy-functionalised dienyl boronates **29** in one-pot tandem Diels-Alder/allylboration reactions.<sup>41</sup> In the case of the 4-methoxy-substituted diene **29**, if the first step occurred at 80 °C in toluene, it was impossible to obtain the allylation products **32**, even by heating at higher temperature or by activation with EtAlCl<sub>2</sub>. By contrast, with the 3-OTES derivative **33**, bicyclic, three-component adducts **36** were isolated in good yields up to 92%. A single diastereomer was detected with maleimide **2a**, the diastereoselectivity being lower with methyl acrylate and vinyl oxazolidinone (Scheme 7).

Scheme 7. Tandem [4+2]-cycloaddition/allylboration of 3- and 4-alkoxy-dienyl boronates.

A one-pot, palladium-mediated cycloisomerisation of ene-ynes **37a-d** was applied to the synthesis of the boronated diene **38a-d**, which was not isolated, but directly used in a one-pot, Diels-Alder reaction/allylboration sequence. This efficiently generated, in high yields, tricyclic structures **40a-k** with control of the four stereogenic centers created (Scheme 8). In the presence of Grubbs II catalyst, a skeletal isomer **41** was produced from **37b**. If the [4+2]-cycloadduct **42** was obtained with *N*-phenyl maleimide **2a**, it failed to give homoallylic alcohols, probably due to steric hindrance.<sup>42</sup>

Scheme 8. Metal-mediated cycloisomerisation/Diels-Alder reaction/allylboration sequence.

An elegant, three-component process was developed by Hilt and co-workers using a cobaltcatalysed Diels-Alder reaction as the key step in a one-pot, cycloaddition/allylboration sequence.<sup>43,44</sup> With (*S*,*S*)-Norphos as chiral ligand, the desired alcohol **45** was isolated in 87% yield and 71% ee (Scheme 9).

Scheme 9. Cobalt-catalyzed Diels-Alder/allylboration sequence.

In a related process, the same group reported a two-steps cascade reaction interconnecting four components to afford dihydroaromatic compounds **48** with a high degree of diastereoselectivity and good yields. After cycloaddition and allylboration, the resulting product was oxidized to afford the corresponding tetrahydronaphthalenes **50** (Scheme 10).<sup>45</sup>

Scheme 10. A two step reaction sequence for the synthesis of tetrahydronaphthalenes 50.

Most of the tandem sequences, in which boron substituted 1,3-dienes were involved, were based on the first Diels-Alder cycloaddition, as shown above. However, a recent report of Norsikian, Beau and co-workers described a novel sequence of tandem transformations which combined the Petasis reaction, intramolecular [4+2]-cycloaddition, cross metathesis and

Michael reaction. This process gave access to new polycyclic heterocyclic scaffolds **58a-f** with good yields and complete stereocontrol (Scheme 11).<sup>46</sup> One year later, the same research team synthesised, based on the same chemistry, more than 30 examples of products with the scaffold as **55**, and proposed a mechanism based on theroretical calculations which supported the involvement of a Diels-Alder reaction occuring through an *endo* approach, with formation of the product with a *cis*-ring junction.<sup>47</sup>

Scheme 11. Tandem sequence based on the Petasis, borono-Mannich reaction as first key step.

Recently, a new sequence using bis-borobutadiene **62** was developped to provide 1,4diaromatic-diol as well as skeleton like **59**, **60** and **61**. The sequence started with an allylboration to provide the allenylboronate species **64** or **67** with high diastereoselectivity. The allenyl boronate intermediate formed during the first step exerted axial chirality with the substituted allenyl moiety and also a stereogenic carbon center. Depending on the nature of the partner used in the sequence, the outcome of the reaction differed. In the case of a monoaldehyde, a second equivalent of aldehyde did react with moderate to excellent enantioselectivity to afford skeleton **68**, whereas the dialdehyde reacted in an intramolecular manner to provide 1,4-diaromatic-diol structure **65** (Scheme 12). In every case, the formation of the major diastereoisomer was explained by steric or  $\pi$ -electron conjugation effects in the Zimmerman-Traxler transition state.<sup>48</sup>

Scheme 12. Reaction of bis-borobutadiene 62 with different aldehydes and dialdehydes.

### II.2. 2-Boron-substituted 1,3-dienes

In contrast to 1,3-dienes functionalised with a boron atom in position 1, only a few studies have been reported on the related dienes substituted in position 2. These compounds are often difficult to synthesise and have, at least for the less substituted derivatives, a strong tendency to undergo Diels-Alder dimerisation even at r.t.<sup>49,50</sup> This process was carefully investigated by Carreaux, Cossio and co-workers with regard to theoretical and experimental aspects.<sup>51</sup> When the dechlorination was carried out in the presence of an aldehyde, the dimer **71** was

immediately converted to the expected homoallylic alcohols **73a-e** in moderate to good yields as mixtures of E/Z-isomers (Scheme 13).

Scheme 13. One-pot tandem dimerization/allylboration reaction of 1,3-diene-2-boronate 69.

In 2005, Welker and co-workers started a series of studies on the synthesis of 2-boronsubstituted 1,3-dienes and their reactivity in tandem reactions, concentrating mainly upon [4+2]-cycloadditions followed by cross-coupling reactions. Potassium and tetra*n*butylammonium buta-1,3-dienyl-2-trifluoroborates **74a-b** were synthesised in good yields from chloroprene and showed no propensity to dimerise.<sup>52,53</sup> Exploration of the reactivity of these dienyl trifluoroborates began with Diels-Alder reactions with ethyl acrylate **75**, methyl vinyl ketone **12** and *N*-phenyl maleimide **2a**. The boron-containing cycloadducts, isolated with high yields, were subsequently cross-coupled using palladium catalysis. A one-pot sequence was also developed, first heating the boron diene with the dienophile, then adding an aryl halide **76**, Pd(OAc)<sub>2</sub> (5 mol%), K<sub>2</sub>CO<sub>3</sub> (3 eq.) and finally refluxing the mixture in EtOH or MeOH for 5 h (Scheme 14). Reactions with various aryl halides **76**, substituted by electron-donating or -withdrawing groups and heteroaromatic halides occurred in moderate to good yields (41% to 64% over two steps) with a preference for the *para*- over *meta*-regioisomers (2.3:1 to 5.7:1 ratio).

Scheme 14. Tandem Diels-Alder/Cross-Coupling reactions of trifluoroborates 74a-b.

Using the same methodology, the preparation and reactivity in tandem Diels-Alder/palladium cross-coupling sequences of a 2-diethanolaminoboron-substituted 1,3-diene **78** were investigated.<sup>54</sup> This diene has proved to be significantly more reactive and more regioselective in [4+2]-cycloadditions compared to the corresponding trifluoroborate. The cycloadducts were then efficiently cross-coupled to iodobenzene **81a**, 4-trifluoromethyl-1-iodobenzene **81b** and 4-iodoanisole **81c**. The regioselectivity observed in the initial Diels-Alder reactions were maintained after cross-coupling (Scheme 15).

Scheme 15. Diels-Alder/cross-coupling reactions of 78.

More recently, new 2-boron substituted 1,3-dienes containing diol and triol ligands were prepared under basic conditions that prevent the dimerisation by-product formation. These four-coordinate boron complexes participated in the same tandem Diels-Alder/Suzuki cross-coupling sequence, which appeared to be palladium-catalysed. The final cycloadducts were obtained in good yields (63% to 83%).<sup>55</sup>

Finally, Welker and co-workers described metal catalysed tandem Diels-Alder/hydrolysis reactions of 2-boron substituted 1,3-dienes.<sup>56,57</sup> Boron-dienes containing various ligands reacted with maleimides in the presence of rhodium and copper catalysts using BINAP as ligand (Scheme 16). NMR analysis of the crude product showed traces of the boron cycloadduct, highlighting that mechanism proceeded, first with a Lewis-acid catalysed [4+2]-cycloaddition, and then by Lewis-acid assisted C-B bond protonation.

Scheme 16. Metal catalysed tandem Diels-Alder/hydrolysis reactions.

In a different approach which exploited another aspect of the reactivity of boron-substituted diene, 2,3-bis[(pinacolato)boryl]-1,3-dienes **86**, synthesised by treatment of 1,1-[bis(pinacolato)boryl]alkenes with excess of 1-bromo-1-lithioethene, was engaged in a triple cascade aldehyde addition.<sup>58,59</sup> 1,5-*Anti*-diols **88a-k** were produced *via* successive diboration, allylboration reactions and finally elimination of boryl and boroxy groups. Four C-B bonds were converted into two C-C and one C=C bonds with total stereocontrol in each step (Scheme 17).<sup>60</sup>

Scheme 17. Synthesis of *anti*-1,5-diols 88 by triple aldehyde addition.

Dienes **89a-d** were synthesised through a hydroboration/vinylidene insertion sequence. The resulting dienes were then used to synthesise the boronic amide derivatives **91a-h**, by addition of *N*-DIBAL aldimine **90a-d**. Oxidative workup followed by hydolysis led to the formation of  $\beta$ -allenylamines **92a-h** with high stereoselectivities in moderate to excellent yields. Products

**92** were employed as precursors for the synthesis of enantiomerically pure *N*-heterocyclic products **94**, **95** and **96** and  $\beta$ -amino acids **93**.<sup>61</sup>

Scheme 18. Preparation of  $\beta$ -allenylamines 92 and their use in the synthesis of enantiopure products.

Another approach based on allenylborane chemistry, using copper(II) catalysed reaction and  $B_2pin_2$  **99** as boron donor, was developped recently to synthesise 2-boron-substituted 1,3dienes **100a-1**. The resulting dienes **100a-1** were then engaged: 1) in Diels-Alder cycloadditions to provide **102a-c**; 2) in Pd catalysed cross-coupling to give **104a-b**; 3) in an oxidation to yield  $\alpha$ , $\beta$ -unsaturated ketone **103**; and 4) in a homologation/allylboration sequence to afford the diene **101** (Scheme 19).<sup>62</sup>

Scheme 19. Preparation of polysubstituted 2-boron-1,3-dienes and their use in different reactions.

### **II.3.** 1-Boron-substituted 1,3-heterodienes

#### II.3.a. 1-Oxo-4-borono-1,3-dienes

In 2003, first examples of a novel diastereoselective routes to  $\alpha$ -hydroxyalkyl dihydropyrans were reported; a sub-structure frequently encountered in the core of a wide-range of natural products.<sup>63,64,65</sup> As in the carbocylic variant, the intermediate cyclic allylboronate **108**, prepared from 3-boronoacrolein **105**, was the key element of a sequential Diels-Alder/allylation. In this case, the catalytic asymmetric version was carried out efficiently in the presence of the Jacobsen's tridentate chromium(III) complex **107** with high diastereo- and enantio-selectivity (Scheme 20).

Scheme 20. Catalytic enantioselective three-component hetero-[4+2] cycloaddition/allylboration sequence.

The first application of this strategy in the synthesis of natural products and analogues concerned (5S,6S)-6-acetoxy-5-hexadecanolide **110**, the oviposition attractant pheromone of a mosquito capable of transmitting the West Nile Virus.<sup>63</sup> Thereafter, several members of the natural styryllactone family **111-114**, displaying cytotoxic and antitumor activities, have been also prepared according to this methodology.<sup>66,67,68</sup> The combination of the catalytic hetero-Diels-Alder/allyboration sequence with a ruthenium-catalysed isomerisation gave access to the 6,8-dioxabicyclo[3.2.1]octane skeleton of (+)-iso-*exo*-brevicomin **115** (Scheme 21).<sup>69</sup>

Scheme 21. Synthesis of natural products using the catalytic enantioselective HDA/allylboration sequence.

When a *Z*:*E*-mixture of 2-substituted enol ethers **116** was used as dienophile, only cycloadducts resulting from a selective reaction of the *Z*-isomer were present in the final product, that prevented the tedious preparation of an isomerically pure starting material. While the second allylboration step required conditions more severe than those employed in the case of ethyl vinyl ether, this approach was successfully applied in the key steps of the total synthesis of a member of the thiomarinol class of marine antibiotics **119** (Scheme 22).<sup>70,71</sup>

Scheme 22. Total synthesis of a thiomarinol derivative 119.

More recently, Hall and co-workers described the total synthesis of a complex 20-membered marine macrolide, palmerolide A **125**, a potent and unusually selective antitumor agent.<sup>72</sup> In this case, the cyclic allylboronate **108'** prepared from the [4+2]-cycloaddition reacted with the starting 3-boronoacrolein **105** which then played the role of the aldehyde partner. The hydroxyl group of the resulting homoallylic alcohol was then engaged in a Claisen-Ireland rearrangement to afford an advanced intermediate **124** for the completion of the total synthesis (Scheme 23).

Scheme 23. Synthesis of an advanced intermediate 124 for the east fragment of palmerolide A 125.

#### II.3.b. 1-Aza-4-borono-1,3-dienes

A few years before the description of the tandem process concerning the 3-boronoacrolein **105**, Hall and co-workers performed a multicomponent reaction involving 1-aza-4-borono-1,3-dienes **126** as key starting materials for the preparation of  $\alpha$ -hydroxylalkyl piperidines **128a-h**. These scaffolds are present in several natural products, particularly in the alkaloid family of palustrine. The tandem process started with the hetero-[4+2]-cycloaddition of an hydrazonodiene with maleimides, as electron-poor dienophiles, followed by an allylboration (Scheme 24).<sup>73</sup> This sequence proceeded with high stereocontrol, as already observed with the carbon and oxygen analogues. In addition, the absolute stereochemistry of the four newly created stereogenic centers were controlled by using a chiral auxiliary (>95% *de* in the case of an *L*-proline derived diene).

Scheme 24. Bicyclic piperidines from tandem aza-[4+2]-cycloaddition/allylboration.

Diversification on the different units, diene, dienophile and aldehyde, has been described. Concerning the maleimide material, substituent R<sup>3</sup> did not exert any significant effect on the process. Other dienophiles have also been tested (acrylates, maleic anhydride), giving no products or unsatisfactory results. A large range of aldehydes, as aliphatic, electron-rich or electron poor benzaldehyde, could be used. Only very hindered aldehydes did not afford any product and both mono- and di-substituted arylhydrazines have proven to give the best yields, probably due to the higher reactivity of the corresponding hydrazones. Furthermore, the double bond of **129b** was selectively hydrogenated under palladium on charcoal, while hydrogenolysis of the hydrazine moiety occurred in the presence of Raney nickel (Scheme 25).

Scheme 25. Hydrogenolysis reactions of hydrazinopiperidines.
Following these results obtained in the liquid phase, Hall and co-workers also examined the suitability of a solid-phase strategy. Finally, due to problems of purity encountered with an *N*-arylmaleidobenzoic acid functionalised resin,<sup>74</sup> or availability of the supported aldehyde partner, a four-component variant of this chemistry was developed in solution phase. The pre-formation of the aza-butadiene component was not necessary and this gave access to a library of 944 polysubstituted piperidines with sufficient purity suitable for biological screening after purification by HPLC with mass-based fraction collection.<sup>75</sup>

The flexibility and usefulness of this chemistry was also demonstrated in target-oriented synthesis with the synthesis of (-)-methyl palustramate and other 2,6-disubstituted piperidines.<sup>76,77</sup> A chiral sulfinimide **133** was used as dienophile and a sequential three component aza-[4+2]-cycloaddition/allylboration/retro-sulfinyl-ene sequence was performed to afford 1,2,5,6-tetrahydropyridine **134** with high regio- and diastereo-selectivity (Scheme 26).

Scheme 26. Tandem aza[4+2]-cycloaddition/allylboration/retrosulfinyl-ene sequence.

#### II.4. Boron-substituted heterodendralene

On the basis of these precedents, boronated 2-vinyl- $\alpha$ , $\beta$ -unsaturated aldehydes **137** were designed to fully exploit the synthetic potential of these classes of organoboranes. These compounds, that can be named boronated [3]-1-heterodendralenes by analogy with the corresponding carbotrienes,<sup>78</sup> allow rapid access to polycyclic heterocycles with control of multiple stereocenters.<sup>79</sup> Thus, sequential Diels–Alder/hetero Diels–Alder reactions (or *vice versa*) can be carried out chemoselectively depending upon the intrinsic reactivity of each 1,3-dienyl system or the order of introduction of the reagents. Furthermore, the allylboronic ester moiety, created in the first cycloaddition step or in the combination of two Diels–Alder reactions, can be engaged in an allylation reaction, which constitutes an additional asset for creating structural diversity (Scheme 27).

Scheme 27. Boronated heterodendralenes 137 in [4+2]-cycloadditions.

As 3-boronoacrolein **105** esters which have been used in metal-catalysed inverse electron demand [4+2]-cycloadditions with enol ethers, **137** reacted with ethyl vinyl ether **106** in the presence of Yb(fod)<sub>3</sub> to afford the corresponding 2-alkoxy-3,4-dihydro-5-vinyl-2*H*-pyran **138**. In the presence of electron-poor alkenes, as *N*-phenyl maleimide **2a**, maleic anhydride **2b**,

activated azo compounds or naphtoquinone, **138** underwent normal Diels–Alder reactions to afford the corresponding cycloadducts **139** as single diastereomers (Scheme 28). These reactions can also be advantageous when conducted in a one-pot process without formation of any product resulting from a first cycloaddition of the 1,3-butadienyl moiety. Various further transformations were then carried out taking advantage of the presence of an allylboronate moiety, for example, oxidation and, more interestingly (in terms of additional diversity), addition to aldehydes, which provided access to the corresponding homoallylic alcohols **142a-c** in 77-86% yields.

Scheme 28. Synthesis of tricyclic imides derivatives.

Alternatively, as the cycloadduct **138** bears a boronic ester group in an allylic position, the allylation and the normal-electron demand [4+2]-cycloaddition steps can be reversed, thus generating supplementary skeletal diversity from the same starting heterodendralene. As an illustration, **138** and 4-nitrobenzaldehyde **35** were allowed to react at r.t. to afford **143**, which underwent a further cycloaddition with *N*-phenyl maleimide **2a** to furnish the single tricyclic compound **144** (Scheme 29).

Scheme 29. Synthesis of 144 via a HDA/allylboration/DA sequence.

The initial boronic ester group of **145**, the direct precursor of **137**, can be also converted into a trifluoroborate substituent by treatment with KHF<sub>2</sub> in MeOH/H<sub>2</sub>O to increase the reactivity of the dienyl moiety towards electron-poor dienophiles. It was directly engaged in a Diels-Alder cycloaddition with *N*-phenyl maleimide **2a** at 50 °C in acetone for 12 h in the presence of various aldehydes to afford diols **147** as major diastereisomers (>95%) and in good overall yields (Scheme 30).

Scheme 30. Diels-Alder/allylboration sequence.

## III. Nitroso derivatives as dienophile

The nitroso hetero-Diels–Alder (HDA) reaction was first described six decades ago by Wichterle<sup>80</sup> and Arbuzov<sup>81</sup> and since then, it has been demonstrated to be a useful chemical tool for the creation of unique structural and functional diversity.<sup>82</sup>

First investigations on this strategy were carried out on arylnitroso derivatives which show higher stability compared to the carbonylnitroso derivatives. In fact, most arylnitroso compounds are stable solids whereas carbonylnitroso does not exist in this form, and need to be prepared *in situ* because of their 1 ms lifetime at infinite dilution.<sup>83</sup> Despite this drawback, carbonylnitroso compounds have been predominantly studied for the last few decades because of their higher versality as nitroso donor reagents. In the next sections, the preparation of the nitroso species will be discussed, and a brief overview of their reactivity and applications in synthesis.

#### **III.1.** Generation of the reactive nitroso species

Arylnitroso species do not require *in situ* preparation and can be directly purchase or easily prepared.<sup>84</sup> Concerning the carbonylnitroso species, numerous approaches were developed in order to further expand the synthetic applications of nitrosocarbonyl Diels-Alder reactions. The most common way to obtain carbonylnitroso derivatives is by oxidation of the corresponding hydroxamic acid derivative. Different oxidation protocols were successfully used such as, periodate,<sup>85</sup> Swern,<sup>86</sup> Dess-Martin,<sup>87</sup> and silver or lead oxide.<sup>88</sup> Later, transition metal catalysed systems based on ruthenium, irridium, vanadium and iron catalysts<sup>89</sup> in

association with peroxides as oxidant, have been used. Recently, milder useful conditions emerged, based on copper salt, and aerobic oxidation in the presence of amine co-catalysts,<sup>90</sup> manganese oxide<sup>91</sup> and photoredox catalysis using either rose bengal or ruthenium catalysts (Scheme 31).<sup>92</sup>

Scheme 31. In situ generation of nitrosocarbonyl compounds.

Other pathways starting from diverse reagents can be also used to generate the carbonylnitroso species **149**, as oxidation of nitrile oxides **151** using NMO,<sup>93</sup> nitrocarbene rearrangement of **153** using rhodium catalyst,<sup>94</sup> retro-Diels-Alder reactions of 9,10-dimethylanthracene cycloadducts **154** under high temperature conditions<sup>95</sup> and photochemical cleavage of 1,2,4-oxadiazole 4-oxides **155** (Scheme 32).<sup>96</sup>

Scheme 32. In situ generation of nitrosocarbonyl compounds using various regaents.

## **III.2.** Nitroso compounds in Diels-Alder reactions

#### III.2.a. Reactivity of nitroso compounds towards dienes

Nitroso compounds are valuable partners in Diels-Alder reactions. However, when the diene **156** possesses an allylic hydrogen (in red on scheme 33), a possible competition could take place between the nitroso Diels-Alder and nitroso ene reactions (Scheme 33). This competition has been pointed out by both Whiting *et al.*<sup>90a</sup> and Alaniz and *et al.*<sup>90b</sup> using carbonyl nitroso derivatives.

Scheme 33. Competition between [4+2]-cycloaddition and nitroso-ene reaction

Even if the nitroso Diels-Alder reaction has been generally accepted as the more rapid reaction compared to the nitroso-ene reaction, three paramaters play a major role in the ratio between the cycloadduct and the ene-product. Firstly, the solvent has a dramatic impact on the ratio between cycloadduct/ene-product, which varies from a 25:1 to a 4:1 mixture. However the origin of this solvent effect remains unclear.<sup>90a</sup> Secondly, the conformations of the diene need to be considered. For the Diels-Alder reaction to take place a *s-cis* conformation for diene is required. A competition study was performed using 1,3-cyclohexadiene and 2,3dimethyl-1,3-butadiene in the presence of a substrate susceptible to undergo an intramolecular nitroso ene-reaction. The study showed that the Diels-Alder cycloadduct was exclusively formed with 1,3-cyclohexadiene (*s-cis* conformation), whereas if 2,3-dimethyl-1,3-butadiene (a mixture of *s-cis* and *s-trans* conformations in solution) was used, the intramolecular nitroso ene-product was predominantly formed (77%). Thus, the conformation of the diene has an important impact as well, and nitroso ene-reaction can be favoured if the reactivity of the diene towards the Diels-Alder was decreased.<sup>90b</sup> Lastly the influence of a possible metalnitroso complex can be considered, esspecially when arylnitroso derivatives are used. Predominant formation of the nitroso ene-adduct, in the presence of a Diels-Alder trapping agent can take place.<sup>97</sup>

#### III.2.b. Regioselectivity of the nitroso Diels-Alder reactions

Kresze *et al.*<sup>98</sup> performed several studies, which indicated that substituted arylnitroso compounds **160a-e** react regioselectively with unymmetric dienes **161a-f**. The regiochemistry of the reaction depends upon the electronic properties of the substituent on the aromatic ring (Scheme 34).

Scheme 34. Regioselective outcome of the reaction between 4-substituted arylnitroso compounds and unsymmetric dienes.

As for the arylnitroso derivatives, some studies<sup>99</sup> have been performed to analyse the behaviour of unsymmetric dienes towards carbonylnitroso compounds in intermolecular nitroso Diels-Alder reactions. The results can be rationalised and features of the carbonylnitroso Diels-Alder reactions can be summarised; Firstly, 1-substituted 1,3-dienes **163** exert better regioselectivity than 2-substituted 1,3-dienes **165**; Secondly, electronic properties of the diene have a major impact; Thirdly for higher selectivity, stronger electronic properties (electron withdrawing or electron donating groups) were required; Lastly, in the case of intermolecular reactions, solvents do not have an important impact on the regioselectivity (Scheme 35).

Scheme 35. Regioselectivity of intermolecular carbonylnitroso Diels-Alder reaction.

#### **III.3.** Some applications of nitroso Diels-Alder reactions

#### III.3.a. Arylnitroso derivatives as dienophiles

A couple of examples using arylnitroso compounds for the synthesis of molecules with biological interests were published. Streith and co-workers<sup>100</sup> prepared the mitomycin skeleton using a sequence starting with a nitroso Diels-Alder reaction between dienal compounds **167a-b** and nitrosobenzene **160a**, to afford compound **168a-b**. A cascade process beginning with an enolisation (b), followed by hetero-Cope rearrangement (c), prototropy and rearomatisation (d), to finish an intramolecular nucleophilic addition and dehydration (e, f) was described to provide **171a-b**. Oxidation (g) using MnO<sub>2</sub> led to the formation of the final compounds **172a-b** (Scheme 36).

reaction conditions: a-f; ethanol (dry), 50 °C, 2 days g;  $MnO_2$ 

Scheme 36. Preparation of the skeleton of mytomycin A.

Danishefsky *et al.*,<sup>101</sup> presented an efficient approach towards the synthesis of the epoxybenzazocine core present in some natural products. For this purpose, a nitroso Diels-Alder reaction using **174** and **175** was used to afford the key intermediate **176** in 70% yield.

Multiple steps including aziridination and Heck arylation, led to the formation of the structure **177** bearing the epoxybenzazocine skeleton **178** (Scheme 37).

Scheme 37. Synthesis of analogues of FR 900482 based on a 2H-1,5-epoxy-benzazocine core.

During the same year, the same group published the total synthesis of mitomycin K **185**.<sup>102</sup> The nitrobenzyl derivative **179** was used as a precursor of the corresponding nitroso compound. First, the (1-methoxy-1,3-butadienyl)lithium **180** was used to prepare the carbinol intermediate **181**. Then, using photochemical redox conditions, nitroso intermediate **182** was formed providing the fused core oxazine **183** by intramolecular nitroso Diels-Alder reaction, which, under these photoredox conditions, was transformed into compound **184** forming the tricyclic scaffold of mytomycin (Scheme 38). No additional explanation has been given to explain the oxidation of the alcohol **182** group into the ketone **183** during the photoredox reaction.

Scheme 38. Synthesis of the precursor 184 for the total synthesis of mitomycin K 185.

The discovery of aminophosphonic derivatives as biologically active molecules led Marchand and co-workers to study the reactivity of 1-phosphono-1,3-butadienes with nitroso derivatives, and especially *o*-nitrosotoluene **160f**.<sup>103</sup> Concise experimental and theorotical studies of the cycloaddition between diene **186a-c** with *o*-nitrosotoluene **160f**, showed that the isomer **187** was predominantly formed. The resulting oxazine **187** possesses multiple sites for functionalisation, namely the N-O bond, the C=C double and the phosphonate moeity. Depending on the sequence used, multiple interesting scaffolds **188**, **189**, **190** and **191** were synthesised (Scheme 39).

Scheme 39. Synthesis of aminophosphonic derivatives.

Recently, a synthesis of protected ( $\alpha$ -branched)-2-pyrrolylamines was described using 1,2dihydropyridine derivatives **192a-j** and nitrosobenzene **160a**.<sup>104</sup> After formation of the Diels-Alder adduct, addition of CuCl (0.2 eq.) in MeOH caused the formation of the pyrrole derivative **194a-j**, by radical N-O cleavage, rearrangement process and final copper mediated oxidation (Scheme 40).

PG = Ac, CBz, PhCO, Tos R = H, CH<sub>3</sub>, Ph, PhCC,  $C_6H_{13}$ , CH<sub>2</sub>COOCH<sub>3</sub>

**Scheme 40.** Protected (α-branched)-2-pyrrolylamines synthesis.

Kirby and co-workers<sup>105</sup> studied the reaction of thebaine, a natural product, with arylnitroso derivatives. All arylnitroso compounds **160** used in these reactions underwent the cycloaddition in good to excellent yields (65-99%). Further modifications of derivative **196a**-**e** emphasised the possibility to handle natural products containing dienes as well as their homologues for futher functionalisation (Scheme 41).

Scheme 41. Arylnitroso Diels-Alder reaction on thebaine 157.

#### III.3.b. Carbonylnitroso derivative as dienophile

Diels-Alder cycloaditions of carbonylnitroso derivatives have been widely studied and numerous synthetic applications have been presented over the years. A few examples from the literature are presented in the next section.

Alkaloid derivatives are interesting targets due to their wide-range of biological activities, and new methodologies are constantly being developed to enlarge the synthesis of these scaffolds. Among the numerous alkaloids known, tropane derivatives **201**, as well as alkaloids from the *Amaryllidecea* family, like narciclasnine **207**, can be prepared *via* intermolecular carbonylnitroso Diels-Alder reactions.

Thus, the total synthesis of (-)-epibatidine has been achieved by Kobayashi and co-workers<sup>106</sup> using chiral carbonylnitroso compound **197** in the presence of the diene **198**. A mixture of

three cycloadducts **199**, **199'** and **199''** was obtained with moderate selectivity. Further modifications of cycloadduct **199'** provided (-)-epibatidine **200** (Scheme 42).

Scheme 42. Total synthesis of (-)-epibatidine 173.

Hudlicky *et al.* presented a synthetic pathway for the total synthesis of narciclasnine **207**.<sup>107</sup> Oxidation of nitroso precursor **203** in the presence of the diene **202** afforded the cycloadduct **204** in 70% yield. A Suzuki-Miyaura cross-coupling using the boronic acid **205** followed by cleavage of the N-O bond provided molecule **206** as a potential intermediate towards the synthesis of narciclasnine **207** (Scheme 43).

Scheme 43. Synthesis of an intermediate for the total synthesis of narciclasnine 207.

The total synthesis of marine alkaloids (-)-lepadin A, B and C from the family decahydroquinoline has been performed starting from **208**.<sup>108</sup> Intramolecular nitroso Diels-Alder reactions led to the formation of a mixture of two diastereoisomers, **209** and **209'**. The ratio between the diastereoisomers was proved to be solvent dependent. By using an aqueous medium, the diastereoselectivity increased towards the formation of isomer **209'**. Subsequent modifications led to the formation of the desired natural alkaloids **211a-c** (Scheme 44).

Scheme 44. Total synthesis of (-)-lepadin A, B and C 211a-c.

Other classes of alkaloids, like molecules bearing a pyrrolidizine core **217** have been synthesised based on such an intramolecular strategy. Yokochi *et al.* were able to achieve the total synthesis of (+)-loline **216** using compound **213** as starting material.<sup>109</sup> A carbonylnitroso Diels-Alder reaction provided bicyclooxazine **214** and **214'** as a mixture of two diastereoisomers. Screening conditions showed that higher temperature gave better yields but lower selectivity. Changing the solvent system from an apolar solvent to an aqueous medium reversed the selectivity of the reaction. The synthesis of (+)-loline was completed after further functionalisations (Scheme 41).

Scheme 45. Total synthesis of (+)-loline 216.

In addition to alkaloid synthesis, different research groups have focused their attention on the synthesis of azasugar and nucleoside derivatives. Miller and co-workers<sup>110</sup> have contributed to this field by developing the preparation of the key intermediate **221**. The synthesis started with the carbonylnitroso Diels-Alder reaction between the chiral nitroso species **218** and cyclopentadiene **219**, providing **220** as the major isomer. A five step pathway using **220** afforded key intermediate **221** in a 36% overall yield. This carbocyclic nucleoside core **221** is present in neplanocin A **222**, aristeromycin **223b** or 5'-noraristeromycin **223a** (Scheme 46).

Scheme 46. Synthesis of key intermediate 221, a precursor to neplanocin A 222, aristeromycin 223b and 5'-noraristeromycin 223a.

Azasugar synthesis can be achieved using nitroso Diels-Alder methodology using asymmetric diene **224a-e** providing oxazine cycloadducts **226a-d** and **226'a-d** in good yields (70-90%) and diastereoisomeric excesses. Dihydroxylation of the major isomers **226a-d** afforded intermediate **227a-d** in moderate to excellent yields. Results of the N-O cleavage reaction are substrate-dependent, and only the compound bearing the following substituents; ( $R^1 = CO_2^{t}Bu$ ,  $R^2 = Me$ ,  $R^3 = OBn$  **227d**), led to the formation of the desired pyrrolidine ring in a 85% yield as a mixture of two diastereoisomers **228d** and **228d'** (80/20) (Scheme 47).<sup>111</sup>

Scheme 47. Synthesis of pyrrolidine azasugar derivatives.

Among natural products containing a diene moiety in their skeleton, steroidal dienes, and more precisely ergosterol, have shown interesting behaviour towards Diels-Alder reactions. This molecule, and other related structures, have been used for years for the design of new biologically active compounds. Thus, Miller and co-workers in 2009 described the reactivity of carbonylnitroso derivative **229a-f** in the presence of ergosterol acetate **230**.<sup>112</sup> By this method, the synthesis of novel  $C_5$  and  $C_8$  disubstituted sterol analogues was achieved. Oxazine **231a-f** was obtained in low to good yields. In fact, the regioselectivity was impacted by the R<sup>1</sup> substituent on the nitroso species **229a-f**. If R<sup>1</sup> was a phenyl or a *p*-Me-phenyl moiety **229a** and **229b** respectively, oxazines **232a-b** were predominantly formed. These compound were never isolated due to a [3,3]-sigmatropic rearrangement which afforded **233a-b** as the major products. In all other cases, regioisomers **231c-f** were obtained as single compounds.

Scheme 49. Functionalisation of ergosterol acetate 230 by carbonylnitroso Diels-Alder reaction.

## Results

# Discussions

## I. Research Plan

The initial research plan was to combine 1-boron-substituted 1,3-dienes and nitroso compounds in pericyclic reactions and to explore the scope and limitations of this chemistry (Scheme 50). In particular, the study of the influence of different parameters towards the nitroso Diels-Alder reaction was envisaged *i.e.*:

- The nature of the boron substituent (hybridisation  $sp^2$  versus  $sp^3$ )
- The electronic properties and the position of the substituents on the diene ( $R^1$ ,  $R^2$  and  $R^3$ )
- The nature of the nitroso partner (arylnitroso and carbonylnitroso derivatives).

The second part of the project was to functionalise [4+2]-oxazine cycloadducts. Indeed, oxazines **236** and **236'** are interesting building blocks giving access to numerous functionalised compounds. Hence, it was envisaged to explore the reactivity of:

- The C=C double bond
- The N-O bond
- The allylborane moiety

By taking advantage of this chemistry, novel synthetic sequences could be considered.

## **II.** Diene syntheses

The syntheses of the dienes used for this study were performed according to different procedures. The choice of one method or the other was mainly driven by the nature of the boron substituent on the final diene and the availability of the starting materials.

#### **II.1.** Enyne hydroboration

Catalytic hydroboration using Schwartz reagent **240** was first used.<sup>113</sup> Starting enynes **238b** and **238c** were commercially available, whereas enyne **238a** had to be prepared starting from  $\beta$ -bromo styrene **237**. Sonogashira cross-coupling using trimethylsilylacetylene **43**, followed by a basic proto-desilylation,<sup>114</sup> led to the desired enyne with a 66% yield as a mixture of two *E*/*Z*-isomers (91/9) (Scheme 51). The ratio *E*/*Z* of the starting **237** has not been checked prior to use, which can explained the formation of **238a** as a mixture of two *E*/*Z*-isomers (91/9).

Scheme 51. Synthesis of enyne 238a.

Hydroboration using pinacolborane **239** of the enynes **238a-c** afforded the desired (*E*)-1,3dienylboronic pinacol ester **241a-c** in good to excellent yields (Table 1). Table 1. Synthesis of 1,3-dienylboronic ester 241a-c by hydroboration.

The second method used for the hydroboration was based on the *in situ* preparation of the di*iso*pinocamphenylborane reagent **244** by mixing  $\alpha$ -pinene **242** with borane dimethyl sulfide complex **243** (Scheme 52).<sup>115</sup>

Scheme 52. Preparation of Ipc<sub>2</sub>BH 244.

Enyne 238c was then directly added to Ipc<sub>2</sub>BH 244, providing exclusively the *E*-vinylborane intermediate 245.<sup>116</sup> The 1,3-dienylborane 245 was converted into the corresponding diethyl 1,3-dienylboronic ester 247 in the presence of a large excess of acetaldehyde 246. This intermediate was used for modification of the boron substituent. In the case of boronic acid MIDA ester derivative 249, a mixture of toluene/DMSO (15/1) was required to obtain a better solubility of the MIDA reagent 248 in reflux conditions.<sup>117</sup> Diene 249 was isolated with an excellent yield of 91%. For the preparation of diene 251, milder conditions were used to observe the total conversion of the compound 247.<sup>118</sup> Despite the fact that diene precipitates out from the reaction, several precipitations and finally a slow crystallisation in a mixture of DCM/Et<sub>2</sub>O were necessary to isolate diene 251 without observing any contamination by remaining diethanolamine. These purification steps explained the low 22% yield (Scheme 53).

Scheme 53. Synthesis of the 1,3-dienylboronic ester 249 and 251.

For the 1,3-diene **252**, the same methodology with  $Ipc_2BH$  was used to afford **252** in an isolated 61% overall yield (Scheme 54).<sup>\*</sup>

Scheme 54. Preparation of diene 252.

The synthesis of the diene **257** bearing a methyl carboxylate function in position 4 was achieved from  $\beta$ -borylacrolein pinacol ester **105**. Hydroboration of propiolaldehyde diethyl acetal **253** using the same procedure as described above for **247** was used, giving after hydrolysis, the boronic acid **254** in a moderate 47% yield. The corresponding  $\beta$ -borylacrolein pinacol ester **105** was obtained by esterification with pinacol in 49% yield. Diene **257** was then synthesised by a Wittig route from an ester-stabilised ylide in a mixture of three stereoisomers (*E*,*E*:*E*,*Z*:*Z*,*E* = 83:10:7, determined by <sup>1</sup>H NMR) in a 81% yield (Scheme 50).<sup>119</sup>

<sup>\*</sup> Reaction performed by previous PhD student (Fabien Tripoteau) and has not been repeated.

Scheme 55. Synthesis of diene 257.

## **II.2.** Dehydrobromination\*

The synthesis of the parent diene was achieved by dehydrobromination of 4-bromobut-1-en-1boronic acid pinacol ester **258**, itself prepared by hydroboration of 4-bromo-1-butene and pinacolborane, with DBU in a 75% yield (Scheme 56).

## **II.3.** Alkyne bromoboration and Negishi coupling\*

The preparation of diene **264** was based on a bromoboration/Negishi coupling sequence.<sup>120</sup> Bromoboration of 1-octyne **260** occured in a *syn* fashion to afford *Z*-2-bromo-1-hexenyldibromoborane, which, in the presence of pinacol **255**, was converted into the corresponding boronate **262** in 81% yield. Negishi cross-coupling with organozinc **263** provided the diene **264** in 46% yield (Scheme 57).

Scheme 57. Bromoboration and Negishi coupling for the preparation of diene 264.

### II.4. Halosulfonylation of 1,3-dienylboronic ester 241c

A halosulfonylation/dehydrohalogenation sequence was used to prepare diene **266**. Sulfonyl halide **265** was added *via* a free radical pathway onto the terminal alkene moiety of the diene **238c**, thus providing the corresponding  $\delta$ -iodobutenyl sulfone. This intermediate was treated *in situ* with triethylamine and the dehydroiodinated compound **266** was obtained as a mixture of two isomers (*E*/*E*;*E*/*Z* = 68;32, determined by <sup>1</sup>H NMR) in a 43% yield (Scheme 58).<sup>121</sup>

Scheme 58. Halosulfonylation of diene 241c.

#### **II.5.** Coupling reaction of vinylboronic acid MIDA ester derivatives

II.5.a. From (E)-2-bromovinylboronic acid MIDA ester

The synthesis of 1,3-dienylboronic MIDA ester was achieved following the Burke *et al.* procedure, involving Suzuki-Miyaura or Stille cross-couplings.<sup>122</sup> *E*-2-Bromovinylboronic acid MIDA ester **267** was subjected to Suzuki-Miyaura cross-coupling with (*E*)-styrylboronic acid **268a**, 1-phenylvinylboronic acid **268b** and *E*-hex-1-ene boronic acid **268c** to yield the desired dienes **269a-c** in 76%, 68% and 50% yields respectively. The aryl substituted boronic acid reagents showed better reactivity compared to the alkyl derivatives. Indeed, a full conversion of starting material was observed using **268a** and **268b**, whereas, **268c** only showed a 63% conversion even with extended reaction times. No optimisation or screening of other catalyst/ligand systems has been undertaken to increase conversion. Non-substituted 1,3-dienylboronic MIDA ester **271** was prepared by Stille coupling using vinyltributyltin **270**, thus affording diene **271** with a satisfactory 72% yield (Table 2).

Table 2. 1,3dienylboronic MIDA ester synthesis by coupling reaction.

II.5.b. From 1-bromovinylboronic acid MIDA ester

The preparation of the 1,3-dienyl-2-boronic MIDA ester **275** started by the preparation of 1-bromovinylboronic acid MIDA ester **274** by bromination of vinylboronic MIDA ester **272** followed by a treatment with DBU (51% yield).<sup>123</sup> Suzuki-Miyaura cross-coupling with 1-phenylvinylboronic acid **268b** showed a conversion of 79%, which is in accordance with the results presented by Burke and co-workers.<sup>123</sup> Purification by silica gel chromatography did

not permit separation of the starting material **274** from the diene **275**. The 30/70 mixture was used in the next step (Scheme 59).

Scheme 59. Preparation of 1,3-dienyl-2-boronic MIDA ester 275.

### **II.6.** Modification of the boron substituents

The preparation of the trifluoroborylated salt **276** was carried out by treatment with potassium hydrogenfluoride **146**, which yielded **276** in 79% yield (Scheme 60).<sup>124</sup>

Scheme 60. Synthesis of the trifluoroboronated diene 276.

## III. Boronated dienes and arylnitroso compounds

## III.1. Reaction of 1-dienylboronate pinacolate esters with arylnitroso compounds

Initial investigations into the nitroso Diels-Alder reaction using the dienyl boronate **241c** and nitrosobenzene **160a** as model substrates resulted in the formation of the unexpected *N*-phenylpyrrole **277a**, instead of oxazine cycloadducts (Scheme 61). Although it is known that 3,6-dihydro-1,2-oxazines can be converted to pyrroles, the conditions employed here (room temperature, no additional reagent, one pot reaction) are clearly different than those already reported: requiring several steps,<sup>125</sup> specific substituents,<sup>100,126</sup> photolysis,<sup>127</sup> high temperature,<sup>128</sup> samarium diiodide,<sup>129</sup> oxidants,<sup>130</sup> basic or acid reagents.<sup>131</sup> Furthermore, even when the reaction was followed by <sup>1</sup>H NMR, only 3-methyl-1-phenyl-pyrrole **277a**, together with some azoxybenzene **278**, was identified. There was a notable absence of any oxazine cycloadducts and the reaction was complete after 5 hours to afford **277a** in 82% isolated yield (Entry 3, Table 3).

Scheme 61. *N*-Phenylpyrrole 277a formation from the reaction of boronated diene 241c and nitrosobenzene 160a.

As shown in Table 3, different arylnitroso compounds **160** do undergo this conversion with boronated diene **241c** to provide the corresponding *N*-arylpyrroles **277**. Yields were moderate to good and the reaction could be conducted either in a protic solvent (MeOH) or an aprotic

solvent (DCM) (Entries 1 and 2, Table 3). A slightly higher yield resulted from an excess of the arylnitroso compound **160** (Entries 1 and 3, Table 3), hence, 2.5 equivalents of arylnitroso compounds **160** were used for most of the reactions. Surprisingly, no significant influence was observed on either the nature or location of the aromatic ring substituent and yields for pyrroles **277a-d**, **f-h** varied from 57 to 82% (Entries 4-9, Table 3).

Table 3. Pyrrole formation from the reaction of arylnitroso compounds 160 with diene 241c.

Entry	Nitroso compound	Product	Yield (%)
<b>1</b> <sup>[a]</sup>	√160a N=O	N-() 277a	67
<b>2</b> <sup>[b]</sup>	160a	277a	61
<b>3</b> <sup>[c]</sup>	160a	277a	82

The parent diene **259** when reacted with nitrosobenzene **160a** gave the corresponding pyrrole **277j** in 78% yield (Entry 2, Table 4).\* However, with a more sterically hindered diene **241b**, there was a significant decrease in yield (16% for the pyrrole **277i**), even after an extended reaction time (Entry 1, Table 4).\* Changing the dienylboronate geometry from *E* to *Z*, as in compound **264**, also had a detrimental effect upon the reaction, with adduct **277k** only being isolated in 34% yield, after 16 h (Entry 3, Table 4).\*

Table 4. Reaction of dienes 241b, 259 and 264 with nitrosobenzene 160a.

<sup>[</sup>a] Reaction with 2.5 eq of ArNO at r.t. for 16 h. [b] Reaction with 2.5 eq of ArNO at r.t. for 5 h.

Next, the influence of substituents on the borodiene was examined. Diene **241a**, bearing a phenyl group, **257** with a methyl carboxylate function, and **266** bearing a sulforyl moiety in position 4, were tested.

In the presence of nitrosobenzene **160a**, no reaction of diene **241a** was observed at r.t. either in toluene or in MeOH (Entries 1 and 2, Table 5). Heating the mixture caused formation of

pyrrole, according to <sup>1</sup>H NMR (Entries 3 and 4, Table 5). The starting nitrosobenzene **160a** was consumed after an extended 22 h reaction time, resulting in 72% conversion of diene **241a** (Entry 5, Table 5). No further improvement was observed if the nitrosobenzene **160a** was added in portions in an attempt to decrease azo-by-product formation **278** (1 eq. at the outset - 1 eq. after 4 h - 0.5 eq. after 4 h), or by slow addition of a MeOH solution by syringe pump (Entries 6 and 7, Table 5). Finally, the use of 3.5 eq. of **160a** (Entry 8, Table 5) was required in order to achieve complete conversion of both stereoisomers of diene **241a**, resulting in the formation of pyrrole **2771** in 36% isolated yield.

Table 5. Study of the reactivity of diene 241a with nitrosobenzene 160a.

Entry	Solvent	Temperature (°C)	Time (h)	Conversion (Isolated yield) (%)
<b>1</b> <sup>[a]</sup>	MeOH	rt	16	0
<b>2</b> <sup>[a]</sup>	Toluene	rt	16	0
<b>3</b> <sup>[a]</sup>	MeOH	reflux	5	50
<b>4</b> <sup>[a]</sup>	Toluene	70	16	50 (14)

The introduction of an electron withdrawing group (ester function) in position 4 of the borodiene was next examined. Diene **257** proved to be even less reactive than diene **241a**, and
longer reaction times and higher temperatures were required to improve the conversion (Entries 1-5, Table 6). In order to form the pyrrole **277m**, 5 eq. of nitrosobenzene **160a** and a 128 h reaction time was required in toluene at reflux, and only the *E*,*E*-stereoisomer reacted. Indeed, even with longer reaction times, the other isomers were still observed in the reaction mixture on the crude <sup>1</sup>H NMR. Nevertheless, 26% of the corresponding pyrrole **277m** was isolated after silica gel chromatography (Entry 5, Table 6).

Table 6. Study of the reactivity of diene 257 with nitrosobenzene 160a.

Entry	Solvent	Temperature (°C)	Time (h)	<i>E,E</i> -isomer conversion (Isolated yield) (%)

[a] Reactions with 2.5 eq of nitrosobenzene. [b] Reaction with 5 eq of nitrosobenzene.

Diene **266** showed the same low reactivity as for the methyl carboxylate derivative **257**. No reaction occured at r.t. in either MeOH or in toluene. Reflux conditions in toluene were necessary to observe the conversion of the *E*,*E*-isomer of **266**. The reaction required 7 days to observe full consumption of this isomer of **266**, whereas the *E*,*Z*-isomer did not show any reactivity. In this case, no pyrrole was isolated, or even observed in the crude reaction mixture by <sup>1</sup>H NMR analysis. Only, the corresponding maleimide **254** was obtained. If the reaction

was performed under argon, 9 days were required to obtain full conversion of the E,E-isomer, which highlighted the possible role of an aerobic oxidation step during the reaction (Scheme 62), but we have hitherto no mechanistic hypothesis to rationalise this result.

Scheme 62. Unexpected formation of maleimide 79.

# III.2. Reaction of tetracoordinated 1-borodienes with arylnitroso compounds

Since the various 1-borodienes with pinacolate esters all resulted in reactions in which the oxazine was not observed, attention was turned to the study of the influence of boron substituents that might result in the oxazine cycloadducts being isolated.

First, attention was devoted to the trifluoroborylated salt **276**. As previously, no oxazine was observed from the reaction of **276** with nitrosobenzene **160a** and the reaction yielded pyrrole **277a** in 79% (Eq. 1, Scheme 63). The replacement of the pinacol ester group **241c** by a diethanolamine moiety was then examined. Reaction of diene **251** with nitrosobenzene **160a** resulted in the identification of the [4+2]-cycloadduct **279** in the <sup>1</sup>H NMR spectrum of the crude mixture. Its structure was confirmed later by comparison of its <sup>1</sup>H spectrum with that of the corresponding MIDA cycloadduct **280a** (Entry 1, Table 7). After 2 h, all the diene **251** was consumed, the intermediate boro-1,2-oxazine **279** had disappeared, and only pyrrole **277a** 

formation was observed, together with small amounts of azoxybenzene **278** (Eq. 2, Scheme 63).

Scheme 63. Reactivity of dienes 251 and 276 with nitrosobenzene 160a.

This increased reactivity of the diethanolamine derivative was confirmed by the reaction of cyclic diene **252** which provided pyrrole **277i** after only 2 h and in a 48% yield as shown in Eq. 2, Scheme 64.

Scheme 64. Comparison of the reactivity between 241b and 252.

Most interestingly was the observation of the transient [4+2]-hetero-Diels-Alder cycloadduct **279** (Eq. 2, Scheme 63) that confirms the key role of the oxazine cycloadduct in the subsequent formation of the pyrrole. Diethanolamine esters are known for their facile hydrolysis or methanolysis to regenerate the corresponding boronic acid or ester,<sup>132</sup> however, simply the reversibility of B-N chelation could be responsible of the facile rearrangement to

the pyrrole (*vide infra*). We can also notice, the beneficial effect of the tetracoordinated boronate ester, which increased the electron density on the diene moiety, and hence, made it more reactive towards the electron deficient dienophile. It is consistent with a "normal" electron demand Diels-Alder [4+2]-cycloaddition.

Prompted by these results, the behaviour of the corresponding MIDA borodiene derivatives 249 was then examined. Because of their high stability towards air and moisture, these compounds have been used as flexible scaffolds for the synthesis of a wide-range of functionalised small molecules.<sup>133</sup> It was our expectation that such dienes would make it possible to isolate and study the intermediate oxazine cycloadducts. The presence of an sp<sup>3</sup>*versus* an  $sp^2$ -hybridized boron species would also be expected to be a useful tool to examine the regioselectivity of the cycloaddition reaction. Hence, the scope of the reaction of the MIDA diene 249 was examined with various arylnitroso compounds 160, as outlined in Table 7. Reactions were carried out in AcOEt to give improved solubility of the B-MIDA diene 249. However, even if the reaction was run in MeOH, the same cycloadduct was observed. The reaction of the MIDA-borodiene 249 provided the corresponding oxazine cycloadducts 280 in moderate to good yields with each of the different arylnitroso compounds 160, without any obvious electronic effects from the aryl substituent. Single regioisomeric products were obtained, as exemplified by the formation of the stable [4+2]-cycloadduct 280a, obtained from reaction of diene 249 with nitrosobenzene 160a and isolated in 64% yield (Entry 1, Table 7). Only the boron-oxygen 1,2-related regioisomer (in red in Table 7) was observed; its structure being assigned by NOESY correlation between the o-phenyl Hs and one of the NCHs on the oxazine ring. The introduction of different arylnitroso substituents, *i.e.* electron donating and withdrawing groups in positions 2 and 4, did not change the resulting regiochemical outcome (Entries 2-5, Table 7) and yields ranged between 47 to 77%. It is also noteworthy that little or no dimerisation of the arylnitroso compounds took place during these reactions, reflecting the short reaction times and more reactive diene, reducing the potential for competitive by-product formation from the nitroso compound. Nevertheless, a second compound was isolated when nitroso **160g** was used. This unknown compound was fully characterised by <sup>1</sup>H, <sup>13</sup>C, <sup>11</sup>B NMR, IR and mass spectroscopy. The molecule possesses a B-MIDA group ( $\delta$  <sup>11</sup>B NMR = 10.3 ppm) and an aldehyde moiety ( $\delta$  <sup>1</sup>H NMR = 9.76 ppm, s, 1H;  $\delta$  <sup>13</sup>C NMR = 185.4 ppm; IR (C=O) stretch = 1743 cm<sup>-1</sup>) and seems to have a pyrrole substructure characterised by small coupling constant ( $\delta$  <sup>1</sup>H NMR = 7.89, d, *J* = 1.7 Hz, 1H; 6.83, d, *J* = 1.7 Hz, 1H). Based on these observations, the structure **281g** was proposed. This observation raises further hitherto unsolved mechanistic questions.

Table 7. Reactivity of MIDA-substituted diene 249 with arylnitroso compounds 160.

[a] Reaction in which the by-product 281g was isolated in 18% yield.

The impact of the substituents on the dienyl moiety, *i.e.* dienes **269a-c** and **271**, was then examined, nitrosobenzene **160a** being used as a model dienophile. The resulting nitroso-addition reactions are summarised in Table 8. Similar to the results observed with the MIDA derivative **249**, the first three dienes (**269b-c** and **271**) gave the same single regioisomeric boron-oxygen 1,2-related products at r.t. (in red in Table 8), with the boron occupying the  $\alpha$ -position relative to the ring oxygen of the oxazine (Entries 1-3, Table 8). The introduction of a phenyl group at C<sub>4</sub> noticeably reduced the reactivity of the borodiene **269a**, with reaction only occurring at reflux in AcOEt over 24 h. In addition, a mixture of regioisomers **285** and **285'** (ratio 40:60) was isolated in an 89% combined yield (Entry 4, Table 8). Both steric and electronic effects of the phenyl ring can explain this observed preferred regiochemistry, as discussed by Houk *et al.* for 1-phenylbutadiene compared with penta-1,3-diene.<sup>134</sup> The structure of the major boron-oxygen 1,3-related regioisomer **285'** (in blue in Table 8) was secured by single crystal X-ray structure analysis (Figure 1), confirming the *cis*-stereochemistry of the boron and phenyl ring substituents.

Table 8. Reactivity of MIDA-substituted dienes 269a-c and 271 with nitrosobenzene 160a.

[a] Reaction with 2.5 eq of nitrosobenzene in AcOEt at rt for 6 h. [b] Reaction with 5 eq of nitrosobenzene AcOEt at reflux for 24 h.

Figure 1. Single crystal X-ray molecular structure of 285'.

## **III.3.** Impact of the boron substituent on the rate of the reaction

Experimental work has proved that the diethanolamine diene **251** is much more reactive than the pinacol ester **241c**. However, no comparisons between dienes **249**, **241c** and **276** could be drawn based on the experimental outcome of the reaction. Thus, an equimolar mixture of **249** and **241c** was stirred at r.t. in the presence of nitrosobenzene **160a** (1 eq.) in MeOD (Scheme 65).

Scheme 65. Study of the reactivity of the diene 249 and 241c toward nitrosobenzene 160a.

After 18 h, the crude mixture was analysed by <sup>1</sup>H NMR (Figure 2). Unfortunately, the sample was not fully soluble in MeOD, so it was impossible to measure accurately the ratio between all the material present in the crude. For a better understanding, the crude reaction mixture was evaporated and diluted with acetone- $d^6$  showing a better, but not total, solubility towards the B-MIDA derivatives **249** and **280a**. Firstly, it was possible to assume that the diene **241c**, pyrrole **277a** and by-products **278** were fully soluble, whereas the B-MIDA derivatives **249** and **280a** were not. According to the analysis, it is possible to conclude that:

- There is no major difference in reactivity between dienes **249** and **241c**.
- The B-MIDA diene seemed to show a slightly higher reactivity based on this results (diene 249/diene 241c 1/2; pyrrole 277a/oxazine 280a 1/1.2).

Figure 2. <sup>1</sup>H NMR study of the diene 249 and 241c toward nitrosobenzene 160a.

A similar <sup>1</sup>H NMR study was undertaken to evaluate the reactivity of the trifluoroboronated salt (Scheme 66). The reaction was performed using diene Bpin **241c** in competition with the diene **276**. Two <sup>1</sup>H NMR analyses were undertaken, one after 10 min and one after 5 h, when the reaction should be finished according to results shown in Table 3. During the NMR sample preparation, trifluoroboronated salt **276** did not show full solubilisation. After 5 min, the <sup>1</sup>H NMR showed that:

- The ratio between pyrrole diene 241c/diene 276/pyrrole 277a = (63/14/23). Diene 276 and pyrrole 277a represented only 37% of the crude product. This observation is not consistent with a full mass recovery from the reaction, with a starting ratio of diene 241c/diene 276 (1/1). It can be explained by the partial solubility of the starting diene 276. Nevertheless, the reaction showed that diene 276 exerted a dramatic faster reactivity or even reacted exclusively with 160a compared to the Bpin variant 241c.
- A small amount of by-products **278** was observed.

After 5 h, only traces of diene 276 were observed, in the presence of pyrrole 277a and diene 241c.

Scheme 66. Reactivity of the trifluoroboronated diene 276 toward nitroso Diels-Alder reaction.

During the reaction presented in Scheme 63, a sample from both reaction (Eq. 1 and Eq. 2) was taken after a few minutes to observe the consumption of the starting diene. BDEA diene **251** showed a 50% conversion after 5 min whereas diene **276** gave a 92% conversion after 10

min. Thus, these two tetracoordinated boron species proved to be more reactive than the Bpin **241c** and the BMIDA **249** variant.

As expected, the boron unit has a dramatic effect on the kinetics of the reaction. The more electron rich the diene is, the faster the reaction is, which is consistent with a "normal" electron, frontier-orbital-controlled [4+2]-cycloaddition reaction. The four boron substituents can be divided in two major groups. The first group involves the Bpin and the BMIDA whereas the second one incorporates the BDEA and the BF<sub>3</sub>K boron unit. The patterns of these empirical observations are comparable to the results of the nucleophilicity parameters calculated by Mayr and co-workers.<sup>135</sup> The reactivity towards nitroso Diels-Alder can be summarised as outlined in Figure 3.

Figure 3. Empirical effects of the boron unit toward the nitroso Diels-Alder reaction.

# III.4. Mechanistic aspects of the reaction 1-borodienes with arylnitroso compounds.

### III.4.a. Computational study<sup> $\dagger$ </sup>

To probe the possible mechanism responsible of the formation of pyrrole **277** from 1boronated diene and arylnitroso compounds **160**, a computational study was carried out using Gaussian 09.<sup>136</sup> The geometries discussed in Schemes 67 and 68 were optimised at the B3LYP/6-31G\* level with no symmetry constraints.<sup>137</sup> The optimised geometries were found to be true minima based on no imaginary frequencies obtained from frequency calculations. The transition-state (TS) geometries were located using the OPT = QST3 method. Frequency calculations on TS geometries revealed one imaginary frequency for each geometry. All intrinstic reaction pathways shown in Schemes 67 and 68 were determined from transitionstate geometries using the IRC command.

#### Regioselectivity of the initial cycloaddition

Among the four transition states in Scheme 67, **TS[ABC]** exerted the lower energy (8.8 kcal.mol<sup>-1</sup>). Calculations showed that the nitrosobenzene **160a** is added through an *endo* pathway with a single regioisomeric boron-oxygen 1,2-related product (in red, Scheme 67).

First the *endo* pathway can be explained by a combination of electrostatic repulsion between the lone pairs of RNO with the electron rich diene and also a repulsive interaction between the *n*-HOMO of the nitroso compound and the  $\pi$ -HOMO of the diene. Secondly, the nitroso

<sup>&</sup>lt;sup>†</sup> Computational studies were performed by Dr Mark A. Fox in the Chemistry Department at Durham University.

Diels-Alder reaction seems to occur through an asynchronous concerted pathway. This has also been postulated by Houk and co-workers, because of the asymmetry of the dienophile.<sup>138</sup>

Scheme 67. Four different pathways and their TS energies determined by computations in the Diels-Alder reaction of nitrosobenzene A and the 1-boronodiene model molecule B.

#### <u>Mechanism</u>

The proposed mechanism involves pyrrole formation proceeding through a Diels-Alder reaction (to give **C**, Scheme 68), followed by a boryl rearrangement (to give **E**, Scheme 68). Then, intramolecular aza-boryl adition to the aldehyde (to give **F**, Scheme 68) and finally borate elimination gives **G** (Scheme 68). All steps were computed to be exothermic thus supporting the cascade process. Eight possible conformers of the oxazine were formed, where; The boryl group occupies either the axial or equatorial position; The phenyl group is either *endo* or *exo*; The oxazine ring is either in a boat or chair conformation. Among the possible conformers, species **C** and **D** are likely products from the favourable Diels-Alder

pathway *via* **TS[ABC]** with **D** as the most stable conformer of all possible conformers of the oxazine. Theoretical results showed that the rate-limiting step in the reaction pathway is likely to be the hetero-Diels-Alder step or the ring cleavage step *via* boryl group rearrangement.<sup>139</sup>

Scheme 68. Possible reaction steps in the formation of 1-phenyl-1H-pyrrole G from a 1-boronodiene model B and nitrosobenzene A.

#### III.4.b.Additional experimental study

Further experimental investigations were then carried out to support this mechanistic hypothesis and the DFT calculations.

The replacement of the pinacol boronate ester on the diene moiety by diethanolamine (*vide supra*) resulted in the identification of the [4+2]-cycloadduct in the <sup>1</sup>H NMR spectrum of the crude mixture. Reacting diene **251** or **276** with nitrosobenzene **160a** for 2 h, resulted in complete diene consumption and even the boro-1,2-oxazine intermediate **279** totally disappeared to afford only pyrrole **277a** with only small amounts of azoxybenzene **278** produced (Eq. 2, Scheme 63). The pyrrole formation under these conditions can be explained by a facile equilibrium between the dioxazaborocane **286** and the corresponding methyl ester **287** due to solvolysis.<sup>132</sup> This equilibrium releases the vacant orbital on boron, and hence, a subsequent rearrangement can occur to access the pyrrole (Scheme 69).

Scheme 69. Proposed mechanism for the formation of pyrroles from the reaction of 1-borodienes with arylnitroso compounds.

The reaction of nitrosobenzene **160a** with the MIDA boronate **269a** results in the formation of the two regioisomers **285** and **285'** which can be separated (*vide supra*). MIDA derivatives can be easily converted to the boronic esters.<sup>133</sup> To confirm the role of the  $B(OR)_2$  in the pyrrole formation, we therefore envisaged to study such transformation with each of the regioisomers by <sup>1</sup>H and <sup>11</sup>B NMR, either under basic or acidic conditions.

#### Under basic conditions

The regioisomer **285** reacted cleanly with (NaOD, 3 eq.) to give the pyrrole **2771**. The proposed reaction sequence for the formation of pyrrole is summarised in Scheme 70.

Scheme 70. Proposed reaction sequence for the formation of pyrrole 2771 from MIDA boronate oxazine derivative 285.

In <sup>1</sup>H NMR spectrum, the starting oxazine **285** showed the features of a B-MIDA substituent characterised by the two sets of signals (dd) between 4.03 and 4.59 ppm. In the <sup>11</sup>B NMR spectrum, there was also the characteristic peak of a tetracoordinated boron species, evidenced by a chemical shift around 10 ppm (10.30 ppm, Figure 4).

Figure 4. <sup>1</sup>H and <sup>11</sup>B NMR of oxazine 285.

After addition of NaOD (3 eq.), <sup>1</sup>H NMR showed the disappearance of the MIDA signal (no signal between 4 and 5 ppm), while, the oxazine scaffold seemed to remain intact. Interestingly, this intermediate was stable overnight under the reaction conditions. <sup>11</sup>B NMR showed a change in boron substituent from a shift at  $\delta = 10.30$  to  $\delta = 0.64$  ppm, which could be consistent with the formation of compound **292** (Figure 5).

Figure 5. <sup>1</sup>H and <sup>11</sup>B NMR of likely intermediate **292** after the addition of NaOD (3 eq.) to oxazine **285**.

Hydrolysis of this postulated borate, using DCl (1 eq.), led instantaneously to a major change in both spectra. In the <sup>1</sup>H NMR, the oxazine scaffold collapsed to provide pyrrole **277l**, while, in the <sup>11</sup>B spectrum, the appearance of a signal at 19.9 ppm is consistent with the formation of (RO)<sub>3</sub>B (Figure 6).

Figure 6. <sup>1</sup>H and <sup>11</sup>B NMR of pyrrole 2771 after the addition of NaOD (3 eq.) and DCl (1 eq.) to oxazine 285.

Under the same basic conditions (NaOD, 3 eq.), regioisomer **285**' gave a mixture of unidentified products.

#### Under acidic conditions

In contrast, under acidic conditions (DCl 1M, 1 eq), 2-phenylfuran **294** was cleanly and quantitatively produced after 10 min at r.t. in acetone- $d_6$ , from regioisomer **285'**, as shown in Scheme 71.

Scheme 71. Furan formation from acidic treatment of oxazine 285'.

As examined on previous systems, this transformation was also followed by NMR. The starting oxazine **285'** showed similar characteristics in both the <sup>1</sup>H and <sup>11</sup>B NMR spectra as for regioisomer **285** (Figure 7).

Figure 7. <sup>1</sup>H and <sup>11</sup>B NMR of oxazine 285'.

Addition of DCl (1.05 eq.) provided formation of the furan **294** in 10 min according to <sup>1</sup>H NMR. No intermediate, as under the basic conditions, was observed. <sup>11</sup>B analysis provided important information concerning the role of the boron in this process. Indeed, none, or only traces of a salt (chemical shift around 0 ppm) was observed, as any by-product resulting from the hydrolysis (chemical shift around 20 ppm). This could mean that a BMIDA derivative was still present in the reaction mixture (Figure 8).

Figure 8. <sup>1</sup>H and <sup>11</sup>B NMR of furan 294 after addition of DCl (1.05 eq.) on oxazine 285'.

To confirm this hypothesis, extraction of the crude mixture with DCM was performed. Byproduct **299** was isolated in 25% yield (Scheme 72), whose structure was established by <sup>1</sup>H (MIDA signals; 4.25 ppm, d, 2H; 4.09 ppm, d, 2H; 3.01 ppm, s, 3H), <sup>13</sup>C (MIDA signals; 167.6 ppm, 2 C=O; 62.1 ppm, 2 CH<sub>2</sub>; 45.8 ppm, CH<sub>3</sub>) <sup>11</sup>B NMR (9.9 ppm), and mass spectroscopy ( $[M+H]^+$  = 249.104). These experimental observations are in agreement with that the proposed mechanism outlined in Scheme 69. A preliminary protonation of the nitrogen atom of the MIDA boronate **285'** results in de-coordination of the nitrogen from boron, leading to the intermediate **295**. Formation of this R-BX<sub>2</sub> moiety **295** then enables a facile boryl rearrangement (**296-298**) to take place, and in this case, to form the furan **294** (Scheme 72).

Scheme 72. Proposed mechanism for the formation of furan 294 from 285'.

It is therefore possible to selectively and cleanly deprotect each regioisomer depending on the reaction conditions. Pyrrole formation was produced from the regioisomer **285** under basic conditions, whereas furan formation occured from **285'** under acidic conditions.

#### III.4.c. The Nitroso Diels-Alder with boronated diene; a reversible process?

The formation of the furan **294** from the second regiosiomer **285'** highlights another feature of the nitroso Diels-Alder reaction, its reversibility.

By comparison of Eq. 1 and 2 shown in Scheme 73, it is important to note that no furan 294 was formed during the reaction of diene 241a with nitrosobenzene 160a. Empirical kinetic studies between diene **249** and **241c** (Scheme 65), as well as previous studies, <sup>135</sup> showed that Bpin and BMIDA seemed to have quite similar electronic effects. Thus, it is plausible to expect that the regiochemical outcome of the cycloadditions should be comparable. However, no furan 294 was formed using diene 241a. There are two possible explanations for this observation. Either regioisomer 300' is highly unstable and decomposed under the reaction conditions, or the nitroso Diels-Alder reaction is reversible. For the first case, decomposition of the regioisomer **300'** could explain the low isolated yield (36%) of pyrrole **2771**. In the case of a reversible process, it might be possible that the retro Diels-Alder reaction of regioisomer 300' occured faster than the rearrangement to provide furan 294, contrary to regiosisomer 300, which was converted instead into pyrrole 2771. Because of the possible reversibility of the Diels-Alder reaction, all reagents involved in the reaction were subjected to decomposition (oxazine intermediate 300 and 300'), polymerisation (diene 241a) or byproducts formation (nitrosobenzene 160a). Unfortunately, no final conclusions could be drawn from this study. Further theoretical calculations relating to this specific case could give important information to support a reversible process.

Scheme 73. Comparison of the reaction between dienes 241a and 269a with nitrosobenzene 160a.

### III.5. Transformations of borono-1,6-dihydro-1,2-oxazine derivatives

To explore the synthetic potential of BMIDA oxazine derivatives, a Suzuki-Miyaura coupling with the cycloadduct **286a**, chosen as a model substrate, was carried out. Under classical experimental conditions for this class of reaction,<sup>133b</sup> <sup>1</sup>H NMR of the crude reaction mixture

showed full conversion of the starting material to the pyrrole **277a**, showing that **286a** was not stable enough to survive the Suzuki-Miyaura coupling conditions (Scheme 74).

Scheme 74. Reactivity of oxazine 286a and iodobenzene 81a under Suzuki-Miyaura coupling conditions.

To confirm that this was indeed the location of the boronated group that was responsible for this failure, the cycloadduct **301** was prepared from diene **275** in a 73% isolated yield with only traces of the second regioisomer. It was engaged in a Suzuki-Miyaura cross-coupling with 1-bromotoluene **302** in the presence of palladium(II) acetate and SPhos (Scheme 75). The 2,4,5-trisubstituted dihydrooxazine **303** was isolated in a 71% yield. A NOESY NMR experiment (correlation between Hs of the methyl group of the toluene moiety and Hs on the oxazine ring at C<sub>6</sub>) established the relationship of groups in this compound, and consequently the orientation of the first cycloaddition. No ring contraction product was observed in this case, but minor amount of the deborylation product were detected. This confirms that the 1-boryl function is essential for the pyrrole or furan formations, through the boryl addition-elimination sequences previously proposed.

Scheme 75. Synthesis of triarylated oxazine 303 from the nitrosobenzene Diels-Alder/Suzuki-Miyaura cross-coupling reaction sequence.

# III.6. The one-pot nitrone formation/1,3-dipolar cycloaddition sequence

The reaction using the Bpin diene **241c** in presence of arylnitroso **160** was previously performed either in MeOH or in DCM without observing any modifications in the outcome of the reaction. Pyrrole **277** was always observed and isolated in 61 to 82% yield (Entries 2 and 3, Table 3). In the case of the BMIDA diene **249**, if initial experiments were carried out in MeOH, AcOEt was finally preferred because of the improved solubility of the starting diene. In both case, the reaction started with a nitroso Diels-Alder reaction (Scheme 76).

Scheme 76. The nitroso Diels-Alder using diene Bpin 241c and BMIDA 249.

#### III.6.a. Nitrone synthesis from 1-dienylboronate pinacolate esters

In order to compare the reactivity of the Bpin and BMIDA dienes, we decided to carry out the cycloaddition of **241c** with the arylnitroso compound **160g** in AcOEt. After 24 h at r.t., analysis of the crude reaction mixture performed by <sup>1</sup>H NMR revealed the presence of an unknown compound **304g** and formation of only a small amount of the expected pyrrole **277g** (**241c**/**304g**/**277g** = 47/50/3). No change was observed after 24 h more.

Scheme 77. Reactivity of diene 241c in AcOEt.

The full consumption of **241c** was achieved by increasing the amount of 4-nitrosobenzoate **160g** (3.2 eq.), the formation of by-products being favoured at higher temperature. Compound **304g** spontaneaously precipitated from the reaction mixture and, after addition of hexane, was then isolated in a 54% yield. Its nitrone structure was established by crystal X-ray analysis.

Figure 9. Nitrone crystal structure for 304g.

Compound **304g** shows the *E*-relationship between the large groups (aromatic ring and the pyrrole substituent). The characteristics of the nitrone functional group are: bond lengths N<sub>1</sub>- $C_{12} = 1.301$  Å and N<sub>1</sub>- $O_3 = 1.2991$  Å, and a bond angle  $O_3$ - $N_1$ - $C_{12} = 121.81^\circ$  in agreement with other similar nitrones described in the literature.<sup>140</sup> Furthermore, the <sup>1</sup>H NMR data are also in full agreement with this structure ( $\delta H_{12} = 8.99$  ppm).

With different arylnitroso compounds **160a** and **160d**, formation of the corresponding nitrones was also observed (Table 9). Nitrosobenzene **160a**, and ethyl 4-nitrosobenzoate **160g** formed around the same amount of nitrone (around 50%) after 24 h. The small differences in the conversion of the starting diene was due to the larger amount of pyrrole **277a** obtained as by-products with nitrosobenzene **160a** (17% > 5%, Entries 1 and 3, Table 9). Thus, to observe if the electronic properties of the subsitution were responsible for the formation of the pyrrole, a reaction with 4-methoxynitrosobenzene **160d** was performed. A larger amount of pyrrole was observed, and a mixture **304d/277d** (52/48) was obtained after 24 h (Entry 2, Table 9). Thus, the ratio of nitrone **304**/pyrrole **277** was modified by changing the electronic properties of the *para*-substituent. When a more electron rich-nitroso species was used, side-reactions giving pyrroles are more competitive, whereas using an electron-withdrawing group (CO<sub>2</sub>Et), **304g** was almost exclusively synthesised (95%). However, with 2.5 eq. of arylnitroso

compounds, the conversion of **241c** ranged only from 53 to 77% after 24 h, and even if the reaction was continued for 24 h, no significant improvement in conversion was observed. In addition to the formation of the pyrrole, standard azoxybenzene by-products **278** were also observed, explaining the moderate conversion. Silica gel chromatography was attempted to purify the nitrone species, however due to their high polarity, isolation of pure compounds was not achieved.

[a] Ratio measured by <sup>1</sup>H NMR analysis on the crude reaction mixture after 24 h with % (Diene + nitrone + pyrrole) = 100.

Analysis of the crude reaction mixture was performed using <sup>1</sup>H NMR spectroscopy. Our attention was focused on the identification of suitable peaks for the measurement of the ratio between the diene, the pyrrole and the nitrone. For diene **241c** (proton in green), pyrrole **277** 

(proton in red) and finally, nitrone **304** (two protons in blue) were used to identify and measure the ratio between the three compounds as shown in Figure 10.

Figure 10. <sup>1</sup>H NMR analysis of the reaction between diene 241c and nitrosobenzene 160a after 24 h.

#### III.6.b. The one-pot procedure nitrone formation/1,3-dipolar cycloaddition

The 1,3-dipolar cycloaddition of nitrones to unsaturated (C-C double or triple bond) compounds is one of the most useful synthetic methods for preparing a variety of heterocycles. It can create as many as three new contiguous stereogenic centres in a single step.<sup>141</sup> The interest of the nitrone formation from a boronated diene and a nitroso compound would be significantly increased if this reaction could be coupled with a [3+2]-cycloaddition. Except **304g**, other nitrones **304a** and **304d** were not isolable by precipitation. Therefore, a one-pot process using various dipolarophiles was envisaged.

The scope of the 1,3-dipolar cycloaddition with N-phenyl maleimide 2a was first studied. In order to enlarge the range of the reaction temperature, AcOEt was replaced by toluene, without affecting nitrone formation. The crude reaction mixture was checked by <sup>1</sup>H NMR after 1.5 h to ensure full consumption of diene 241c. The N-phenyl maleimide 2a was then added and the mixture was stirred at 90 °C for 16 h. Nitrosobenzene 160a and 4nitrosobenzoate 160g afforded a mixture of the endo/exo-isomers 305/305' with a ratio around 50/50 (Entries 1 and 2, Table 10). The diastereoisomers were readily separated by silica gel chromatography. When the arylnitroso was para-substituted by a halogen (Cl or Br), the endo-isomer 305 was only observed (Entries 3 and 4, Table 10). Nevertheless, the same low yields between 20 and 30% were obtained. In contrast, para-methoxy nitrosobenzene 160d didn't show any formation of the oxazolidine, even if the corresponding nitrone was observed by <sup>1</sup>H NMR, before addition of the maleimide (Entry 5, Table 10). Lastly the orthonitrosotoluene 160f, showed the formation of an endo/exo-ratio 305/305' of 67/33. However, only the endo-isomer was isolated in a very low yield (12%) (Entry 6, Table 10). According to these results, it seemed that the substitution on the aryl moiety of the nitroso had a major impact on the selectivity of the cycloaddition reaction. Further studies are required to rationalise these observations.

Table 10. Scope of the arylnitroso for the oxazolidine synthesis.

305a',b',d',f',g',h'

Unlike *N*-phenyl maleimide **2a**, diethyl azodicarboxylate **307** (DEAD) and dimethyl acetylenedicarboxylate **308** (DMAD) did not show any formation of the desired product resulting from the [3+2]-cycloaddition, either, at r.t. or under reflux conditions. Only hydrolysis of the nitrone intermediate was observed, affording the corresponding aldehyde **306g** in low yield (27 to 43%) (Entries 1-3, Table 11).

**Table 11**. Screening of the dipolarophile for the [3+2]-cycloaddition.

Entry	Nitroso	Dipolarophile	Temp. (°C)	Time	Isolated yield (%)
1		Eto N	reflux	18 h	33%
2	EtO <sub>2</sub> C 126g	EtO N O 307	r.t.	72 h	43%
3	N=O	O MeO 308	reflux	22 h	27%

#### Identification of the endo- and exo-isomers

The *endo-* and the *exo-*isomers **305** and **305'** respectively showed two different <sup>1</sup>H NMR patterns. The protons from the oxazolidine structures were easily identifiable thanks to their chemical shift, but mainly thanks to their different coupling constants.  $H^A$  is a doublet of doublets with two close coupling constants of J = 8.1 and 8.6 Hz, which was consistent with

the coupling constant measured for the other signals for H<sup>B</sup> and H<sup>C</sup> of the oxazolidine. When all the protons are on the same face on the structure (*exo*, molecule in red in Figure 11), all coupling constants are in the same range, *i.e.* between 8 and 9 ppm. On the other hand, the second isomer (*endo*, molecule in blue in Figure 11), H<sup>C</sup> was on the opposite face from H<sup>A</sup> and H<sup>B</sup>, leading to a major change in the coupling constants. Indeed, whereas H<sup>A</sup> still had a coupling constant  $J_{H^{-},H^{B}}^{A} = 7.5$  Hz, the second coupling constant was small *i.e.*  $J_{H^{-},H^{-}}^{A} = 0.9$  Hz.

Figure 11. Comparison of the <sup>1</sup>H NMR of the *endo*- and the *exo*-isomer.

The identification of the isomers was confirmed by obtaining crystal structures of **305b** and **305a'** (Figure 12).

Figure 12. Oxazolidine crystal structures of 305b and 305a'.

#### Preliminary optimisation of the nitrone formation/1,3-dipolar cycloaddition

Despite the fact that novel highly functionalised oxazolidine structures were synthesised, the low overall yield remained a handicap for future synthetic applications. Even if the diene **241c** was always consumed entirely during the nitrone synthesis, the highest yield observed for the 1,3-dipolar cycloaddition was only 26% yield (Entry 3, Table 10). This can be due to the instability of the nitrone under high temperature conditions or to the quality of the diene used for the optimisation of the reaction. Therefore, another batch of freshly prepared diene was subjected to the same reaction conditions. No sample was taken after 1.5 h and the *N*-phenyl maleimide **2a** was directly added. After 16 h at 90 °C, the oxazolidine product were obtained in 66% within a ratio of *endo/exo* (55/45), *i.e.* comparable to the ratio obtained in Entry 2, Table 10. However another compound was observed in the crude <sup>1</sup>H NMR analysis of the reaction mixture, *i.e.* a signal at  $\delta = 5.80$  ppm suggested that the unknown product was the result of the Diels-Alder reaction of **2a** with the starting diene **241c** (Scheme 78). This
observation led to reconsideration of the methodology developed for the nitrone formation, because this implied an incomplete conversion of the diene. After purification, both isomers were isolated and separated with a combined 40% overall yield.

Scheme 78. One-pot oxazolidine synthesis with new batch of diene 241c.

#### III.6.c. Mechanistic aspects

## The nitrone formation

The formation of the nitrone derivatives using boronated dienes and arylnitroso compounds obviously raises numerous questions about the reaction mechanism, namely the order of the different steps and the type of mechanism involved in the sequence.

The most common way to synthesise nitrone derivatives is by condensation of hydroxylamine with an aldehyde. However, a few examples have been described decades ago, using arylnitroso derivatives as nitrone precursors.<sup>142</sup> The nitrone synthesis has not been fully explained, but most of the studies agreed on a nitroso-ene reaction as the first step, followed by an oxidation. An alkenyl aryl nitroxide was detected by ESR spectroscopy,<sup>143</sup> highlighted the possibility of the nitroso-product as an intermediate. More recently, another work presenting nitrone formation using arylnitroso derivatives as precursors has been published.<sup>144</sup>

Three pathways could be envisaged to describe the formation of the nitrone, based on three different reactions: a Diels-Alder/rearrangement process; an arylnitroso-ene reaction; and an oxidation (Scheme 79).

Scheme 79. Pathways envisaged for the nitrone formation.

Preliminary studies to ascertain a plausible mechanism started with the pathway shown in green in Scheme 79. If the hypothesis of a first Diels-Alder/rearrangement reaction was in process, reaction of the pyrrole **277g** in the presence of nitroso compound **160g** (2.2 eq.) should provide the nitrone in AcOEt at r.t. No reaction occured after 24 h and no azoxy by-products **278** were observed either (Scheme 80). Thus, the first step of the cascade process is unlikely to be pyrrole formation, and moreover, the absence of by-products, emphasised the influence of the boron moiety on the formation of azoxybenzene and other by-products from the nitroso species, possibly due to Lewis acid activation.

Scheme 80. Reaction of pyrrole 277g with nitroso 160g.

Thus, the cascade process had to begin with the formation of the arylnitroso ene adduct **310**. This observation proved that the boron substituent on the 1,3-diene was necessary for the sequence to take place. If the same type of reaction was performed using isoprene **186** in benzene, only the standard [4+2]-cycloaddition occured to yield the oxazine cycloadduct **313** in 42% (Eq. 1, Scheme 81).<sup>145</sup> In contrast, when the diene **241c** was used, it showed that nitrone **304** was predominantly synthesised (Eq. 2, Scheme 82).

Scheme 81. Comparison of the reaction of nitrosobenzene 160a with isoprene 186 and diene 241c.

Another set of reactions was then engaged to improve and determine the most probable oxidation pathway. A standard reaction using normal conditions was performed as a reference, in order to check the conversion after 1.5 h with the one batch of diene used for the later reactions. The conversion obtained after 1.5 h was 77% (Entry 1, Table 12). In order to improve the oxidation step, mild aerobic radical conditions were tried. Thus, a reaction using TEMPO in stoichiometric amounts led to full conversion of the starting diene after 1.5 h

(Entry 2, Table 12), whereas catalytic amounts (0.1 eq.) exerted only a slight improvement of the conversion (85%, Entry 3, Table 12) compared to the reference reaction (77%, Entry 1, Table 12). Hence, full oxidation could be obtained only under those conditions. Further investigations to find a suitable work-up procedure are still in progress. An anaerobic reaction was undertaken to determine whether oxygen was responsible for the partial oxidation, however the nitrone **304g** was also formed in around the same amount (74%), making the aerobic oxidation unlikely.

**Table 12.** Study of the oxidation step.

Bpin + (1 eq.) 241c	EtO <sub>2</sub> C (3.1 eq.) <b>160g</b>	EtO <sub>2</sub> C	s EtO <sub>2</sub> C $S$		
	Entry	Reaction conditions	Conversion after 1.5 hours <sup>[a]</sup>		
	1 <sup>[b]</sup>	AcOEt, r.t.	77%	_	
	2 <sup>[b]</sup>	AcOEt, r.t. TEMPO (1 eq.)	100%		
	<b>3</b> <sup>[b]</sup>	AcOEt, r.t. TEMPO (0.1 eq.)	85%		
	4 <sup>[b]</sup>	AcOEt, r.t. inert atmosphere (Ar)	74%		

[a] Conversion measured by <sup>1</sup>H NMR. [b] Reaction using the same batch of diene **241c**.

The second possibility envisaged was that one of the arylnitroso by-products forming during the reaction was responsible for the oxidation step. To support this hypothesis the reaction between **315** and **160g** was undertaken under the nitrone formation conditions (synthesis of **315** will be discussed in the next Chapter). A sample was taken after 1.5 h and analysed by <sup>1</sup>H NMR showing numerous products had been produced, and no final conclusions concerning the formation of the nitrone could be made (Scheme 82). Nevertheless, two signals at  $\delta = 8.97$  and 8.95 ppm were observed, which could be consistent with alkenyl protons from the nitrone

moiety. Possible formation of the *trans*- and the *cis*-isomers could explain the two signals. As a comparison, the nitrone alkenyl protons for **304g** showed a  $\delta = 8.99$  ppm chemical shift. Furthermore, a large amount of starting material was still remaining in the reaction mixture. If the reaction was continued for 22.5 h, no changes were observed.

Scheme 82. Oxidation study on the starting material 315.

The oxidation step seemed to be performed by arylnitroso by-products, formed during the reaction. AcOEt and toluene had a dramatic influence towards the formation of the nitrone product. However, no reasonnable explanation has been found to explain the change in reactivity related to the modification of the solvent. Further reactions need to be performed to ascertain the order of the cascade process.

### The 1,3-dipolar-cycloaddition

The 1,3-dipolar cycloaddition has been generally accepted as a concerted asynchronous pericyclic cycloaddition. In the case of nitrone compounds as dipoles, both HOMO-LUMO interactions mode could occur because of the close energy gap in each case. The HOMO (dipole) can pair with the LUMO (dipolarophile), and *vice versa*. The diastereoselectivity of the cycloaddition towards the formation of either the *endo-* or the *exo-*isomer is mainly driven by two factors. The first one is the  $\pi$ -interaction between the aromatic ring of the nitrone

(dipole) and the carbonyl group of the *N*-phenyl maleimide **2a** (dipolarophile), and the second one is the steric hindrance generated by the aromatic ring (Scheme 83). In this case, the diastereoselectivity is dependent on the substituent of the aromatic ring, and the  $\pi$ -interaction seems to be predominant. Indeed, the formation of the *endo*-isomer was always slightly, or exclusively favoured (Table 10). Nevertheless, the difference in diastereoselectivity between each case remained unclear.

Scheme 83. Mechanism and selectivity of the nitrone [3+2]-cycloaddition.

## **III.7** Summary

This study revealed that hetero Diels-Alder cycloadditions of arylnitroso compounds and 1boronated dienes afford either pyrrole derivatives or oxazine cycloadducts. The most critical parameter to guide these reactions remains the ability of the boron to keep, or not, its sp<sup>3</sup>hybridization state. The presence of a boronate function  $\alpha$  to the oxygen or the nitrogen atom of the oxazine ring is responsible of the ring contraction. Different experimental observations, in addition to theoretical investigations, led to a mechanistic proposal to rationalise these results. First, the nitroso Diels-Alder reaction took place in a regioselective asynchronous concerted manner. Then, formation of the pyrrole derivative can be explained by a boryl rearrangement, followed by an intramolecular aza-boryl to aldehyde addition and borate elimination. In the case of 2-MIDA boronodienes, the formation of the corresponding [4+2]-cycloadduct is also highly regioselective. No decomposition of the oxazine ring was observed during a Suzuki-Miyaura coupling. A 2,4,5-triaryl-3,6-dihydro-1,2-oxazine was isolated in good yield, thus showing why this approach to prepare these class of heterocycles with complete control of the position of the different substituents could be valuable.

Following these observations, an unexpected and interesting nitrone formation was demonstrated, just by modifying the solvent of the reaction between 1,3-dienylboronate **241c** and arylnitroso derivatives **160**. Taking advantage of this reactivity, a one-pot procedure starting with nitrone formation followed by a "normal" electron demand Diels-Alder reaction was developed to afford functionalised oxazolidines in modest yields. Unfortunately, the scope of the Diels-Alder reaction remained limited to *N*-phenyl maleimide as dipolarophile. The exact mechanism of this process remained unclear and further investigations are necessary both to rationalise these experimental results and to improve the overall yields of this sequence.

# IV. Boronated dienes and carbonylnitroso compounds

Following the previous study and as part of the research programme developed by our group on the chemistry of carbonylnitroso compounds,<sup>90a</sup> we next turned our attention to the reactivity of two compounds (**318a** and **318b**) toward dienylboron substrates (Scheme 84).

Scheme 84. Reactions of boronated dienes with carbonylnitroso compounds.

# IV.1. Reaction of 1-dienylboronate pinacolate esters with carbonylnitroso compounds

Due to their high instability, the carbonylnitroso species need to be prepared *in situ*. The most common way to generate these carbonylnitroso sepcies is to oxidise the corresponding *N*-hydroxycarbamate **318a** or hydroxyurea **318b**, respectively. The study started by determining a suitable oxidation system which could be used in the presence of the different boronated dienes. Diene **241c** was used as the model substrate because the Bpin variant is presumed to be the most sensitive boron moeity towards oxidation, compared to a BMIDA substituent for example.

The most common oxidation procedure involves periodate as the oxidant.<sup>82</sup> As expected, these strong oxidation conditions led to the formation of numerous compounds, and more

importantly to the degradation of the boron part of the starting diene. Photoredox conditions, developed by Tan and co-workers,<sup>92a</sup> using Rose Bengal dye as catalyst, showed formation of a unique compound bearing a new diene unit. No pyrrole formation, from the previously described Diels-Alder-rearrangement process, was observed. However, only a 25% conversion of the starting nitroso precursor **318a** was observed and no improvement was observed if the reaction time was extended or by using a larger amount of Rose Bengal. A major drawback of this method was that an excess of the diene **241c** (3 eq.) was used.

Thus, attention was then focused on aerobic copper-catalysed oxidation. Two different, recently developed systems were tried. The first one used  $\text{CuCl}_2^{90a}$  and the second one  $\text{CuCl}_{,}^{90b}$  both conditions being tested with pyridine as co-catalyst. Copper(I) exerted a faster reaction compared to the copper(II) derivative. Indeed, after 16 h at r.t., the reaction using CuCl as a catalyst showed a 71% conversion of the starting diene **215c**, whereas by using CuCl<sub>2</sub>, only a 11% conversion was observed. Three products were observed in the crude reaction mixture (Scheme 85).

Scheme 85. Study of the reaction between diene 241c and carbonylnitroso precursor 318a.

The compounds were identified as:

• The ene adduct **315** as the major product which was isolated and fully characterised;

- The pyrrole **319**, resulting from the Diels-Alder/rearrangement process of the ene adduct **315** previously formed. Isolation of pyrrole **319** was not done and the proposed structure was based on the NMR analysis;
- The pyrrole **320** resulting from the the Diels-Alder/rearrangement process of the starting diene **241c**. It was identified by <sup>1</sup>H NMR spectroscopy and comparison with literature data.<sup>146</sup>

A screening of the reaction conditions was undertaken in order to optimise the formation of the ene-product. Non-polar or halogenated solvents (toluene, DCM) led to a decrease in reactivity. In both cases, conversion after 16 h was around 10% (Entries 3 and 4, Table 13). The ene-compound was the major compound (> 80%) after 184 h. Polar solvents increased reactivity (THF, MeCN and acetone) with a conversion between 56 and 70% after 16 h (Entries 1, 2 and 5). If acetone was used, the selectivity towards the formation of 315 decreased drastically. If the reaction was not stopped before 30 h, either decomposition or formation of by-products was observed using TLC. A protic solvent (MeOH) favoured formation of numerous by-products, thus, the ratio between 315/319/320 was impossible to determine (Entry 6, Table 13). The use of pyridine as co-catalyst gave cleaner reactions and better yields, while using 2-ethyloxazoline was detrimental (Entry 7). If the reaction is faster with CuCl, better selectivity towards formation of the ene-compound 315 was observed with  $CuCl_2$ , compared to the CuCl version (96% > 82%, Entries 1 and 8). Modifying the catalyst loading allowed the optimisation of the selectivity towards the ene-adduct **315**. By decreasing the catalyst loading from 20 to 10 or 5%, a slight improvement in the selectivity was measured (82 to 90 to 94%, Entries 10 and 11). When CuCl (0.05 eq.) was used, the reaction was slower (Entry 11). Conversion after 16 h was decreased by 14% compared to the reaction with 10 and 20%. It is also important to mention that the reaction needed to be carried out between 10 and 20 °C. If the temperature exceeded 25 °C, the ene-compound was never

isolated as a white solid and in fact, degradation occurred, <sup>11</sup>B NMR analysis showed numerous species.

Tableau 13. Optimisation of the nitroso-ene reaction.	
---	--

[a] Reaction performed with 0.4 mmol of starting diene, 20 mol% of catalyst and 5 mol% of co-catalyst. [b] Reaction performed with 0.4 mmol of starting diene, 10 mol% of catalyst and 2.5 mol% of co-catalyst. [c] Reaction performed with 0.4 mmol of starting diene, 5 mol% of catalyst and 1.25 mol% of co-catalyst. [d] Conversion measured by <sup>1</sup>H NMR.

Finally, using the best conditions [CuCl (0.1 eq.), pyridine (0.025 eq.) in THF at 15 °C in presence of air], the reaction was scaled up (Scheme 86). The average yield over three runs on a 2.6 mmol scale was 51% with a range of 3%; a small decrease being observed compared to Entry 10 in Table 13.

Scheme 86. Medium scale ene reaction.

To check whether the synthesis of the ene-compound was substrate dependent, the second nitroso precursor **318b** was used under the aerobic reaction conditions. The reaction was performed with CuCl (0.2 eq.) and pyridine (0.05 eq.), because the first attempt using same optimised conditions as described in Entry 10, Table 13, did not show useful results. By modifying the heteroatom in the  $\alpha$ -position of the carbonyl group (O replaced by NH), a total change in reactivity was observed. No ene-adduct was observed in the crude reaction mixture and only pyrrole **321** was identified. After purifiaction by silica gel chromatography, **321** was isolated in a low 16% yield (Scheme 87).

Scheme 87. Synthesis of pyrrole 321 using nitroso precursor 318b.

# IV.2. Reaction of tetracoordinated 1-borodienes with carboylnitroso compounds

A major impact of boron substituents was previously demonstrated in the case of nitroso Diels-Alder reactions of 1-boronodienes with arylnitroso compounds. Changing the boron hybridisation from sp<sup>2</sup> to sp<sup>3</sup> enabled the isolation of stable oxazines. A similar behaviour was observed with carbonylnitroso precursors **318a-b** and the BMIDA diene **249**. The nitroso Diels-Alder reaction occured selectively to provide only the 1,2 related boron-oxygen regioisomer (in red in Table 14), as for arylnitroso compounds, to provide the oxazines **322a** and **322b** in moderate to good yields 58 and 72%, respectively. The reactions being performed in THF, the BMIDA diene **249** was not fully soluble, that can explain the long reaction times (7 and 9 days). Stronger oxidation conditions (tetrabutylammonium periodate) decreased significantly the reaction time from 9 days to 2 hours when **318a** was used, but also the final isolated yield 37% (Table 14).

Table 14. Regioselective formation of stable oxazines from carbonylnitroso Diels-Alder reactions.

[a] Reaction using the copper aerobic system CuCl (0.2 eq.), pyridine (0.05 eq.) in THF at r.t. [b] Reaction using Bu<sub>4</sub>NIO<sub>4</sub> (1.2 eq.) in DCM at - 5 °C.

As previously observed, in comparison with the Bpin derivative, the  $BF_3K$  diene **276** exerted faster nitroso Diels-Alder reactivity. Pyrroles **320** and **321** were isolated in moderate yields (48 and 53% respectively, Table 15). No competitive ene-adduct was formed.

Table 15. Reactivity of trifluoroborylated diene 276 and carbonylnitroso.

# **IV.3.** Mechanistic aspects

### IV.3.a. The aerobic copper oxidation step

The mechanism of aerobic oxidation of the nitroso precursor is proposed to be based on a  $Cu^{I}/Cu^{II}O$  catalytic cycle (Scheme 88).<sup>147</sup> Different oxidation pathways can be envisaged related to the  $Cu/O_2$  stoichiometry leading to numerous catalytic species.<sup>148</sup> In most of these reactions, aromatic nitrogens are often used as electron-donating ligands. The nature of the ligand (monodentate or polydendate), as well as the number of ligand attached to the copper center, have been shown to be responsible for the geometry adopted by the Cu-complex.<sup>148</sup> In the system used for the nitroso-ene reaction, pyridine was used as a monodentate ligand. Most of the studies on the topic have proposed the cupric superoxo species ( $Cu^{II}-O-O^{\bullet}$ ) as the initiator of the oxydation by hydrogen abstraction.<sup>149</sup> Copper(I) chloride has proved to give the best results, leading to a fast catalytic cycle, which is in accordance with kinetic results obtained by Deng *et al.*<sup>150</sup>

Scheme 88. Simplified aerobic oxidation mechanism of the nitroso precursor.

## IV.3.b. The Diels-Alder/ring contraction sequence

In the presence of the BMIDA dienes **249** and  $BF_3K$  **276**, the reactivity of the carbonylnitroso compounds was similar to the arylnitroso derivatives. Firstly, a regioselective Diels-Alder reaction took place to form the 1,2-related boron-oxygen regioisomer oxazine cycloadduct (in red in Scheme 89). In the case of the diene boronated MIDA ester **249**, the oxazine was stable and could be isolated after chromatography. For the trifluoroboronated salt **276**, the rearrangement (already described in the Chapter 2) slowly provided the pyrroles **320** and **321**. Only a slight difference in rate was measured, especially with diene **249**, nitroso **323b** reacting faster (7 days) than nitroso **323a** (9 days).

Scheme 89. Proposed mechanism for the formation of the oxazine and pyrrole.

### IV.3.c. The ene reaction: Impact of the boron substituents

The results obtained with diene **241c** showed two different reactivities based on the nature of the heteroatom in the  $\alpha$ -position of the nitrosocarbonyl group. When the carbonylnitroso was an urea-type (as in compound **323b**), only formation of the pyrrole was observed, presumably *via* the same mechanism as presented in Scheme 89 with diene **276**. On the other hand, the carbonylnitroso bearing an oxygen atom instead of nitrogen, provided predominantly the ene-compound **315**, with only traces of Diels-Alder adduct (Scheme 90). To our knowledge, only transition-metal-catalysed Alder-ene reactions involving boronic esters have hitherto been reported to date.<sup>151</sup>

Scheme 90. Pyrrole 321 versus ene 315 formation.

The ene reaction is a pericyclic reaction involving an alkene bearing an allylic hydrogen (the enepartner, *e.g.* **329**) and a molecule containing an electron-deficient multiple bond (the enophile, *e.g.* partner **328**). During the process, a new  $\sigma$ -bond between C<sub>3</sub> and C<sub>4</sub> (in red in Scheme 91), an ene  $\pi$ -bond migration from C<sub>3</sub>-C<sub>2</sub> to C<sub>2</sub>-C<sub>1</sub> (in blue in Scheme 91) and a hydrogen shift from C<sub>1</sub> to C<sub>5</sub> (in green in Scheme 91) can occur, affording acyclic compound **330**.

Scheme 91. The ene reaction.

Whereas, the ene-reaction has been described as a concerted, but potentially asynchronous reaction, the exact mechanism of the nitroso-ene still remains unclear. Indeed, the reactivity is directly dependant upon the electronic properties of the reactive partners, and specifically the HOMO-LUMO gap, which is very small for nitroso compounds. The discovery of the nitroso-ene reaction was first reported in 1910 by Alesandri,<sup>152</sup> the first real study was accomplished later by Knight and co-workers.<sup>142</sup> Six different mechanisms have been postulated to

rationalise the course of this reaction (Scheme 92). The first one involves a concerted synchronous or asynchronous pericyclic transition state **331**. This transition state is allowed by the Woodward-Hoffmann selection rules as a  $[\pi 2s + \pi 2s + \sigma 2s]$  process (path A).<sup>153</sup> Other possible pathways involve aziridine *N*-oxides (ANO) **332** (path B)<sup>154</sup> and diradicals **333** (path C).<sup>155</sup> Pathways involving zwitterion **334** (path D) and (pathway E and F) have also been postulated. The last two mechanisms involve a highly strained oxazetidine **335** or two radical species **336** and **337**,<sup>156</sup> which appears the most unlikely.

The first computational work was carried out using PM3 by Davies and Schiesser on propene and nitrosyl hydride.<sup>154a</sup> They presented two major possible intermediates, and according to the results of the concerted pathway A, it appears that the carbon-nitrogen bond can be almost fully formed before the allylic hydrogen transfer. This observation is consistent with a highly asynchronous mechanism. Nevertheless, they also found that the ANO intermediate **332** described in pathway B provided a lower energy barrier of 8 kcal mol<sup>-1</sup> compared to the concerted pathway. Later, another study using the B3LYP/6-31g\* basis set for their DFT calculations on the nitroso ene mechanism, supported the assumption that the reaction can go through an aziridine *N*-oxide intermediate as the rate determining step.<sup>154b,c</sup> Houk and coworkers presented another pathway based on a polarised diradical intermediate **333** (pathway C) using B3LYP/6-31g\* DFT calculations.<sup>155</sup> Formation of this polarised diradical intermediate was characterised by high energy rotation barriers of carbon-nitrogen and carbon-carbon bonds (4-5 kcal.mol<sup>-1</sup>) resulting from an attack of nitrosyl hydride on a propene molecule. The diradical formed during the rate determining step, can then abstract an allylic hydrogen to either form the ene-compound or equilibrate to the aziridine *N*-oxide **332**.

Studies on the regioselectivity of the nitroso ene reaction have also been performed, but in the case of the monosubstituted substrate (olefin bearing the methyl group on **241c** in this study), only the hydrogen from the methyl group can be transferred.<sup>157</sup>

Scheme 92. Possible mechanism for the nitroso ene reaction.

With the trifluoroborate **276** the nitroso Diels-Alder/rearrangement process occured in moderate yields to afford pyrroles regardless the nature of the carbonylnitroso species. By contrast, with a more electron-deficient diene (pinacol ester **241c**), the course of the reaction was governed by the nature of the heteroatom in  $\alpha$ -position of the nitrosocarbonyl group. By modifying the HOMO-LUMO gap, the rate of Diels-Alder reaction decreased drastically, and, as a result, with **318b**, only pyrrole **321** was isolated. If the substituent on the nitroso compound has higher electron-withdrawing character, only traces of Diels-Alder cycloadduct was detected, and ene adduct **315** was predominantly isolated.

# V. The ene-adduct as key intermediate in cascade reactions

The ene-compound **315** is a polyfunctional molecule with multiple sites for further modifications and therefore can be envisaged as a valuable intermediate for the synthesis of different scaffolds, especially in the field of bioactive compounds. This work focused on:

- the diene (in blue on Figure 13)
- the OH of the hydroxycarbamate (in red on Figure 13)
- the boron unit (in green on Figure 13)

-

Figure 13. Ene-compound 315.

# V.1. The Diels-Alder/allyboration sequence

The tandem Diels-Alder/allylboration process has been developed to afford numerous scaffolds.<sup>158</sup> It gives access to molecules with a high degree of complexity in a minimum number of steps. Most of the time, the outcome (stereoselectivity and regioselectivity) of the Diels-Alder cycloaddition is directly related to the electronic properties and the steric influences of both the diene and dienophile. In the case of "normal" electron-demand Diels-Alder reactions, electron-poor dienophiles usually react through an *endo* transition state. In the case of organoboron compounds, this reaction has been successfully coupled with an

allylboration, which is also widely used in organic synthesis because of the high stereocontrol.<sup>159</sup>

In the case of the diene **315**, such a sequence could provide bicyclic compounds **340**, with control of up to four stereocentres, one of them being quaternary (Scheme 93).

Scheme 93. The Diels-Alder/allylboration sequence on the compound 315.

#### V.1.a. The Diels-Alder step

Before envisaging a one-pot procedure, screening of different dienophiles was performed on the ene-adduct **315** to determine its reactivity. In the case of the *N*-phenyl maleimide **2a**, reaction was complete after 24 h in DCM to afford the compound **339a** in 84% isolated yield after silica gel chromatography (Entry 1, Table 16). When maleic anhydride **2b** was used, the reactivity decreased, giving 77% conversion after 44 h in DCM at r.t. and 62 h were necessary to obtain full conversion of the starting compound **315**. Unfortunately, compound **339b** was never isolated due to stability issues. Standard silica gel, deactivated silica gel with  $Et_3N$  (2%) and florisil chromatographies or precipitation using different solvent mixtures in different ratios were all unsuccessful (Entry 2, Table 16). Concerning methyl acrylate **12** and *p*benzoquinone **341**, no reaction was observed at r.t. in DCM after 44 h. The solvent was then changed for a higher boiling point solvent, and reactions took place in toluene when heated at 90 °C. In the case of *p*-benzoquinone **341** and methyl acrylate **12**, no starting material **315** was recovered, but no characteristic peaks of cycloadduct were observed either (Entries 4 and 5, Table 16). Lastly, the dienophile 4-phenyl-1,2,4-triazole-3,5-dione **23** was tested. <sup>1</sup>H NMR of the crude reaction mixture showed full consumption of the starting ene **315** in 24 h, but <sup>11</sup>B NMR showed formation of another boron species, instead of the Bpin moiety alone. A peak for boroxine ( $\delta = 22$  ppm) was observed (Entry 3, Table 16).

Reactivity of **315** is therefore highly dienophile dependent. For the reaction to take place, a highly electron-deficient dienophile such as maleic anhydride or related structures is required. This preliminary study highlighted the question of stability of the diene **315**, as well as cycloadduct **339**, under high temperature conditions.

 Table 16. Diels-Alder reaction of the compound 315.

It has already been reported that Lewis acids can catalyse Diels-Alder reactions.<sup>32,43,44,56,57</sup> Except for *N*-phenyl maleimide **2a**, all the other dienophiles tested in Table 16 exerted low or no reactivity at all. To counter this problem, various catalysts were tried with no significant improvement. The conversion after 48 h, measured by <sup>1</sup>H NMR, ranged from 68 to 85% (Table 17).

A possible explanation of the inactivity of catalysts, could be the presence of the free alcohol of the hydroxycarbamate on the compound **315**, which might coordinate to the Lewis acid. Hence, a *O*-acetyl protected version **342**, of the ene compound **315**, was synthesised following the reaction conditions described in Table 23. No catalytic effect was observed and only around 50% conversion was only observed after 48 h at r.t. proving that **342** is even less reactive than **315**.

Concerning the stereochemical outcome of this cycloaddition, different attempts at crystallisation were tried on compound **339a** without success. Its structure was determined by analysis of the coupling constants in correlation with calculated values obtained by conformational searches using Spartan '10 (see Experimental section).<sup>‡</sup> Calculated values did not permit assurance of the structure of the cycloadduct. None of the isomers showed all of the coupling constant values within a reasonable margin of error. Nevertheless, comparisons of the coupling constants  $J_{\text{H1-H2}}$  (Hz) and  $J_{\text{H3-H4}}$  (Hz) led us to the *endo*-structure. In the case of the *endo*-isomer, calculated coupling constants were,  $J_{\text{H1-H2}} = 5.4$  Hz and  $J_{\text{H3-H4}} = 5.1$  Hz and for the *exo*-isomer  $J_{\text{H1-H2}} = 2.2$  Hz and  $J_{\text{H3-H4}} = 1.7$  Hz. The comparison with the measured constants ( $J_{\text{H1-H2}} = 5.8$  Hz and  $J_{\text{H3-H4}} = 4.1$  Hz) is therefore in favor of an *endo*-isomer. Furthermore, comparison with data published on a related cycloadduct,<sup>30</sup> suggested also the formation of the *endo*-isomer.

#### V.1.b. The Diels-Alder/allyboration one-pot process

In order to evaluate the possible advantage of a one-pot sequence, a comparison with a process wherein the two reactions were carried out separately was undertaken. As observed in Table 16, *N*-phenyl maleimide **2a** showed the best reactivity, and thus was used as model dienophile with *p*-nitrobenzaldehyde **35** an electron-deficient aldehyde. For the one-pot procedure (Eq. 1, Scheme 94), the reaction was carried out in toluene at 60 °C for 66 h. The crude reaction mixture showed a mixture of unreacted *N*-phenyl maleimide **2a**, *p*-nitrobenzaldehyde **35**, and pinacol **255**, as well as the desired compound **340a**. It is worthy to note that no compound **315** or cycloadduct intermediate **339a** were observed. The crude product was purified by silica gel chromatography to recover *N*-phenyl maleimide **2a** in 15% yield and *p*-nitrobenzaldehyde **35** in 52%. The desired product **340a** was isolated in 40% yield.

On the other hand, the same sequence was carried out with isolated compounds (Eq. 2, Scheme 94) which afforded only a 16% overall yield. The Diels-Alder step led to the formation of the [4+2]-cycloadduct in 84% yield (Entry 1, Table 16), whereas the allylboration, using the same reaction conditions (toluene, 60 °C, 66 h), provided compound **340a** with a 19% isolated yield, proving that allylboration is the critical step in the sequence. The one-pot procedure is therefore preferred for the following study the most suitable pathway (40% > 16%).

Scheme 94. One-pot procedure *versus* isolated method.

A screening of the reaction conditions was undertaken to define the influence of the solvent, stoichiometry of the reactants, the concentration and the temperature. At r.t., with a concentration of 0.17 mol.L<sup>-1</sup> of **315**, the solvent did not show a major impact in either the Diels-Alder or the allylboration step. Toluene showed a slightly better reactivity, with a

higher 315 consumption and allylation compound 340a formation (Entry 2, Table 20). More importantly, formation of two allylation compounds, 340a and 340a', were observed after 72 h and 1 week. Even if acetone did give the lowest conversion towards the [4+2]-cycloadduct, it seemed that the allylboration step was slightly faster, compared to the reaction using CDCl<sub>3</sub> and MeCN  $d^3$  (Entries 1, 3 and 4). In order to evaluate the impact of the temperature, toluene and acetone were chosen as solvents. By increasing the temperature to 50 °C and 80 °C, the cycloaddition and the allylboration were faster. However, the ratio between the two allylation compounds 340a and 340a' were modified depending on the temperature. At r.t., the reaction in toluene afforded the compounds 340a and 340a' in a ratio of (66/34) after one week (Entry 2). At 50 and 80 °C, the ratios were respectively (49/51) and (54/46) (Entries 5 and 6). When acetone was used, and the reaction was heated at 50 °C, the same characteristics were observed. Higher temperature enhanced the reactivity, and modified the ratio of allylation compounds 340a and 340a' (100/0 at r.t., 81/19 at 50 °C) (Entries 3 and 9). In addition to the temperature, concentration also had a dramatic impact upon reactivity. If the concentration was increased approximately five-fold from [315] = 0.17 M to [315] = 1.00 M, the conversion towards the cycloadduct intermediate and also the allylation were increased (Entries 8 and 10). With acetone, good selectivity was observed after one week with a ratio of (90/10).

Based on these observations, the outcome of the reaction (conversion and ratio) was shown to be highly concentration and temperature dependant. Furthermore, a polar solvent (acetone) gave a faster allyboration reaction. Data showed that the allylboration step was the ratedetermining step. Thus, the number of equivalents of the aldehyde partner in the reaction was increased. The impact was not as important as for the concentration and the temperature, but 2.1 eq. of aldehyde provided the best compromise between reactivity and selectivity with 92% conversion, and a 93/7 ratio after 45 h. Because of the lack of reactivity of some dienophiles (Table 16), a reaction in DMSO at 140 °C was undertaken. Unfortunately, only decomposition of starting materials was observed.

 Table 20. Optimisation of the one-pot Diels-Alder/allylboration sequence.

[a] Ratio measured by <sup>1</sup>H NMR of the crude reaction mixture. [b] <sup>1</sup>H NMR not determined.

The results presented in Table 20 were all calculated using <sup>1</sup>H NMR on the crude reaction mixture. Below are presented two NMR analyses (Figure 14 and 15); one containing only one allylation compound **340a** and a second with a mixture of both compounds **340a** and **340a'**. In acetone, when the NMR was clean enough, attention was focused between the 5.5 and 6.5 ppm region. The remaining **315** compound was characterised by a doublet ( $\delta = 5.68$  ppm, J = 18.6 Hz), the cycloadduct **339a** by a multiplet ( $\delta = 6.02$  ppm), and compound **340a** by a doublet of doublet ( $\delta = 6.30$  ppm, J = 10.2, 2.8 Hz).

**Figure 14.** <sup>1</sup>H NMR analysis of the crude reaction mixture in acetone after 72 h.

In toluene, due to the formation of a second isomer, identification of the different compounds involved in the reaction was more tedious. In addition to the area between 6.5 and 5.5 ppm, it was necessary to study a second set of signals between 3.5 and 2.4 ppm. Remaining **315** compound was characterised by a doublet ( $\delta = 5.79$  ppm, J = 18.6 Hz, not visible on Figure

15), the cycloadduct **339a** by a multiplet ( $\delta = 6.11$  ppm), compound **340a** by a multiplet ( $\delta = 2.88$  ppm) and compound **340a'** by a doublet ( $\delta = 3.36$  ppm, J = 15.0 Hz).

**Figure 15.** <sup>1</sup>H NMR analysis of the crude reaction mixture in toluene after 7 days.

Depending on the conditions, formation of a single allylboration compound **340a**, or a mixture of **340a** and **340a'**, were observed. The structure of the major isomer was established according to spectroscopic data (NMR and mass), the determination of the X-ray structure of of the related compound **350** (page 131) and by comparaison with literature data.<sup>30</sup> This stereochemistry can be explained by the formation of an *endo* cycloadduct during the Diels-Alder step and an allylboration transition state where the aryl substituent of the aldehyde occupied the equatorial position of a chair-like conformation (Scheme 95).

Scheme 95. Stereochemical outcome of the cascade reaction.

A screening of the dienophile and aryl aldehyde was then carried out. *N*-phenyl maleimide **2a** was first used as the dienophile in the presence of different arylaldehydes. Isolated yields after silica gel chromatography were low to moderate (16 - 48%). This was directly related to the electronic properties of the aldehyde, *i.e.* if  $R^1$  was an electron withdrawing group, the allylboration step was accelerated, by increasing the relative positive charge on the carbonyl group. On the other hand, the opposite behaviour was observed with  $R^1$  as an electron donating group.

The same pattern was obtained using maleic anhydride **2b** as dienophile. Better yields were obtained using maleic anhydride **2b**, because no silica gel chromatography was required for purification, since the precipitation of the major compound was observed in CHCl<sub>3</sub> overnight at + 4 °C. Concerning the structures of these products, as it was already reported in the literature,<sup>30</sup> intramolecular cyclisation can occur to afford lactone derivatives. To determine whether the cyclisation occured, a <sup>1</sup>H NMR comparison between **340a** and **345b** in DMSO-*d*<sup>6</sup> was performed. For **340a**, the hydroxycarbamate signal ( $\delta = 9.69$  ppm, s) and alcohol signal ( $\delta = 5.92$  ppm, d) were identified, by D<sub>2</sub>O exchange. In the case of **345b**, only one signal, corresponding to the hydroxycarbamate signal ( $\delta = 9.53$  ppm, s) was detected. Concerning IR analysis, attention was focused on the region between 1600 and 1800 cm<sup>-1</sup>. Compound **345b**
showed the peak with the highest intensity at 1730 cm<sup>-1</sup>.  $\delta$ -Valerolactone (a 6-membered lactone) showed a peak with the maximum of intensity at 1722 cm<sup>-1</sup>. Furthermore, IR data resulting from the cycloaddition using maleic anhydride has been described, and the C=O bond was measured at 1770 cm<sup>-1</sup>.<sup>160</sup> Thus according to these data, it was most probable that the product resulting from the reaction using maleic anhydride **2b**, was the lactone **345** resulting from the intramolecular cyclisation. Also, two azo compounds were tested 4-phenyl-1,2,4-triazole-3,5-dione **23** and DEAD **307** leading to a decomposition of the starting **315**.

 Table 21. One-pot Diels-Alder/allylboration sequence using arylaldehydes.

Entry	Dienophile	Aldehyde	Isolated Yield (%)
1	O l/	4-nitrobenzaldehyde <b>35</b>	<b>340a</b> 48
2	N-Ph	Benzaldehyde <b>4</b>	<b>340b</b> 39
3	2a	4-anisaldehyde <b>39a</b>	<b>340c</b> 16
4		4-nitrobenzaldehyde <b>35</b>	<b>345</b> a 75
5	7 2b	Benzaldehyde 4	<b>345b</b> 64
6		4-anisaldehyde <b>39a</b>	345c -
7	0 N N N Ph 0 <b>23</b>	4-nitrobenzaldehyde <b>35</b>	-
8		4-nitrobenzaldehyde <b>35</b>	-

Attention was then turned to  $\alpha$ , $\beta$ -unsaturated aldehyde as partner of this three component reaction. When acrolein **346** was used, the expected polycyclic products **340d** and **345d** were synthesised according to crude <sup>1</sup>H NMR (Entries 1 and 3, Table 22). Nevertheless, only **340d** was isolated in 37% yield (Entry 1). Interestingly, if *trans*-cinnameldehyde **347** was employed, the reaction afforded the spirocyclic oxazine compounds **349a** and **349b**, using *N*-phenyl maleimide derivatives (Entries 2 and 5). With maleic anhydride **2b**, the spirocyclic oxazine scaffold evolved to form compound **350** as already postulated in Table 21. When a D<sub>2</sub>O exchange was performed on molecule **349a**, the signal corresponding to the alcohol disappeared proving that no cyclisation had occured.

**Table 22.** One-pot Diels-Alder/allylboration sequence using  $\alpha$ , $\beta$ -unsaturated aldehydes.

The preparation of a suitable crystal in the case of compound **350** allowed determination of the exact structure of this polycyclic heterocycle by X-Ray analysis, which is confirmed by  ${}^{1}$ H and  ${}^{13}$ C NMR spectra. By analogy, we were able to deduce the structures of the related products **349a-b**.

Figure 16. Crystal structure of compound 350.

#### V.1.c. Mechanistic aspects

The proposed mechanism starts with a Diels-Alder/allylboration sequence described in Scheme 95. On the basis of Alexanian and co-workers study,<sup>161</sup> a mechanism based on an aerobic ketooxygenation was proposed. As an initiation step for the radical reaction to take place, they hypothesised that a small amount of the amidoxyl radical **352** was formed by an autooxidation process. A second alternative could be a boron-catalysed initiation process. The oxygen radical then cyclised to give the oxazine ring **353** by a 6-*exo*-cyclisation process with creation of a carbon-centered radical as a single diastereoisomer. Formation of a stabilised benzylic radical can explain the formation of the 6-membered ring. Radical oxidation with  $O_2$  afforded the radical intermediate **354** which initiate the propagation by a hydrogen abstraction

from the substrate **351** yielding radical **352** and producing intermediate **354**.<sup>161</sup> Whereas the conditions described in the paper used Ac<sub>2</sub>O (1 eq.) and DMAP (0.1 eq.) for the elimination step, in our case no external reagent was necessary to observe the same reactivity. A homolysis of the peroxide intermediate **355** could occur and by abstraction of the benzylic hydrogen, could provide the compounds **349a,b**, releasing water. When maleic anhydride was used as dienophile, an intramolecular lactonisation ended the sequence.

### V.2. Modification of the boron substituent

The boron substituent has an impact on the rate of the Diels-Alder reaction. No catalytic effect had been observed with compound **315** bearing a Bpin substituent, thus, it was envisaged that modification of the substituent on the boron would impact the reaction. The trifluoroboronated salt **356a** was synthesised using the procedure with potassium hydrogenbifluoride **146**. The desired compound **356a** was obtained with 89% yield. An attempt to synthesise the MIDA derivative using the standard procedure used for the preparation of the diene **249** was unsuccessful. Compounds **315** and **248** were recovered from the reaction. Lastly, the diethanolamine derivative was synthesised. Mixing compound **356b**. Therefore, the reaction was carried out at high temperature under neat conditions in a distillation apparatus. Pinacol **255** was directly distillated during the process at 80 °C. Then, excess of diethanolamine was removed by increasing the temperature from 80 °C to 120 °C. <sup>1</sup>H NMR and <sup>11</sup>B analyses of the crude reaction mixture showed formation of the desired compound.

Scheme 99. Effects of modification of the boron substituent on 315.

No advanced research on the Diels-Alder reaction was performed, but thanks to a probable higher reactivity towards the Diels-Alder reaction, cycloaddition using **356a-b** with other dienophile could provide a wider range of cycloadducts. Moreover, purification could be facilitated, because most of the products bearing a trifluoroborate moiety could be easily precipitated out from the crude reaction mixture.

## V.3. The metathesis/arylnitroso Diels-Alder/ring contraction sequence

Attention to diversify the chemistry of **315** was then turned to the hydroxycarbamate part of the molecule. The presence of this easily derivatisable group should allow a supplementary functionalisation and, therefore, greatly increase the structural diversity accessible from this ene product.

#### V.3.a. Synthesis of the O-substituted hydroxycarbamates

Two different derivatisations were performed, both of them resulting in the introduction of an additional unsaturation to the dienyl moiety, as summarised in Table 23. In the case of allyl bromide, in the presence of DBU, the reaction yielded **362a** in a 49% yield after silica gel chromatography (Entry 1, Table 23), whereas, after classical workup, only polymerised compound was recovered with acryloyl chloride (Entry 4). The same problem was encountered by scaling up the reaction from 0.15 mmol to 0.5 mmol using allylbromide since only 9% of the desired compound **362a** was isolated (Entry 2). It is known that boronated dienes have strong tendency to polymerise. This drastic decrease in yield was suppressed by using 2,6-di-*t*-butyl-*p*-cresol (BHT) as a stabiliser to inhibit the auto-polymerisation of the polyene and rapid filtration over a pad of silica. With these experimental conditions, the isolated yield of **362a** increased from 9 to 85% (Entry 3), and, similarly, the acryloyl derivative **362c** was isolated in 70% yield (Entry 5). Propargyl derivative **362d** was prepared *via* the same method in an isolated 60% yield (Entry 6). **361c-d** could be stored in dark in the fridge (4 °C) under an inert atmosphere, without observing any polymerisation.

Table 23. Synthesis of protected hydroxy carbamate adducts.

Entry	Base	organohalide	Product	Isolated yield (%)
1 <sup>[a]</sup>	DBU			49
2 <sup>[b]</sup>	DBU	Br 357a	Ph O N Bpin	9
3 <sup>[c]</sup>	DBU		358a	85
3 <sup>[a]</sup>	Et <sub>3</sub> N	Ο		56
<b>4</b> <sup>[b]</sup>	Et <sub>3</sub> N	CI	Ph O N Bpin	54
5 <sup>[b]</sup>	DBU	357b	∬ <b>342</b>	55
6 <sup>[a]</sup>	Et <sub>3</sub> N	Q		0
7 <sup>[d]</sup>	DBU	357c	Ph O N Bpin O 358c	70
8 <sup>[d]</sup>	DBU	Br 357d	Ph O N Bpin O 358d	60

[a] Reaction performed with 0.15 mmol of compound **315** without optimised purification conditions. [b] Reaction performed with 0.5 mmol of compound **315** without optimised purification conditions. [c] Reaction performed with 2.00 mmol of compound **315** with optimised purification conditions. [d] Reaction performed with 0.5 mmol of compound **315** with optimised purification conditions.

We also tested the same functionalisation with the trifluoroborate **356a**, dichloromethane being replaced as solvent by acetone to increase the solubility. The <sup>1</sup>H and <sup>11</sup>B NMR analysis of the crude product indicated that the reaction took place, however several attempts at precipitation using different solvent mixtures (DCM/Et<sub>2</sub>O, DCM/hexane, acetone/Et<sub>2</sub>O, acetone/hexane) in various ratios failed. Therefore, a second pathway was envisaged starting from the Bpin derivative **315**. First, the allylation was performed, and after full conversion of

the starting material, the modification of the boron substituent was tested based on the same procedure used for the synthesis of **276** (Scheme 60). Analysis of the crude product showed the same results and same purification issues as the first method (Scheme 100).

Scheme 100. Synthesis of the trifluoroborylated allylated compound 359.

### V.3.b. The ring closing metathesis (RCM) of hydroxamates 358a-c

Metathesis is a reaction which allows the formation of new carbon-carbon double bonds by the reaction of two alkenes. This reaction has been widely developed, and nowadays, numerous catalysts have been developed to enhance the reactivity and the scope of the reaction.<sup>162</sup> Among them, the most well-known catalysts are summarised in Figure 18.

Figure 18. Most used metathesis catalysts.

The ring closure metathesis (RCM), one of the olefin metathesis processes, is one of the most efficient strategies used for the synthesis of cycle, heterocycle and macrocycle compounds.<sup>162j</sup>

Scheme 101. General formation of cyclic compounds by RCM.

### The ring closure metathesis (RCM) for oxazine ring formation: bibliographic data

Several examples have already been reported in the field of oxazine derivatives. Tae and coworkers<sup>163</sup> showed that the RCM can be performed on both Boc and Bz-protected substrates **370** yielding the desired oxazines compound **371** in moderate to excellent yield (63 - 93%). The Boc-protected acryloylamide derivative was subjected to the same reaction conditions, and 6- and 7-oxazine ring **373a-b** were obtained with high yields (> 80%), whereas the formation of the 8-membered **373c** ring did not take place (Scheme 102).

Scheme 102. Synthesis of oxazine using catalysed Grubbs I 360 RCM.

An interesting outcome was pointed out experimentally by Le Flohic *et al.*, with the allylic substrate **370a**, *i.e.* the reaction using **361** afforded the oxazine with an excellent 96% yield, whereas the acryloyl derivative **374** did not exert any reactivity with either **360** or **361** in toluene or DCM at r.t. or 70 °C (Scheme 103). Moreover, according to literature work, the nitrogen needed to be substituted by an electron withdrawing group to enable reactivity.<sup>164</sup>

Scheme 103. Differences in reactivity between 370a and 374 towards the RCM.

The formation of the bicyclic  $\beta$ -lactams **376** using Grubbs' second generation catalyst **361** for ring-closing metathesis was found to depend on ring size (Scheme 104). It is worthy to note that the metathesis reactions involving Grubbs' first generation catalyst **360** gave no product formation.<sup>165</sup> A few other examples were presented in the literature for the synthesis of a library of cell-permeable molecules, or aminoalcohol derivatives.<sup>166</sup>

Scheme 104. RCM on derivatives 375.

An elegant sequence using this process was presented, starting with the enyne metathesis, followed by a [4+2]-cycloaddition with singlet oxygen to afford cyclic peroxides fused with an oxazine ring **379** (Scheme 105).<sup>167</sup>

Scheme 105. Sequence enyne metathesis/Diels-Alder cycloaddition.

#### The ring closure metathesis (RCM) of hydroxamates 358a-c

The last example has shown the potential of a sequence metathesis/Diels-Alder sequence for oxazine synthesis. The diene **351** could be an interesting substrate for a ring closure metathesis reaction (RCM) between one of the carbon-carbon double bond of the diene and the allyl moiety making possible a further Diels-Alder step. Two products could be obtained depending on the selectivity on this ring closure process: the 6-membered oxazine ring **374**, thus forming a 1,3-boronated diene or a 7-membered ring **375** with an exocyclic alkene (Scheme 106).

Scheme 106. Possible outcome of the RCM on compounds 358a.

Grubbs catalyst (2<sup>nd</sup> generation, **361**) was selected to study the reactivity of **358a**. Previous works on the RCM has proved that reflux conditions in DCM and high dilution favoured the cyclisation over the polymerisation. Thus, concentrations used for the reactions were varying between [358a] = 0.05 and 0.07 mol.L<sup>-1</sup>. A reaction did take place with non-stabilised 358a and 10 mol% of the catalyst over 24 h, forming a single compound according to crude <sup>1</sup>H NMR analysis (Entry 1, Table 24). After silica gel chromatography, compound 380 including a 1,3-boronated diene moiety was isolated in 61% yield. However, the methodology developed for the synthesis of protected hydroxycarbamate involved BHT as inhibitor to circumvent stability issue. Therefore, the metathesis was tested using derivative 358a incorporating 14% of BHT. To our satisfaction, no impact was observed between the reaction with stabilised and non-stabilised 358a (Entries 1 and 2) and both reaction yielded the same compound in around 60% yield. The catalyst loading was then reduced and a slight improvement of the yield was observed with 5 mol% of the catalyst providing 380 with 70% yield. If the loading was decreased to 3 mol%, isolated yield decreased by 4% to reach 66% (Entries 3 and 4). When the reaction was scaled-up with 3 mol%, a small, but measurable, decrease of the isolated yield was observed (Entry 5). It was also noteworthy that 380 is stable on silica gel chromatography. As a result, BHT and presence of by-products from the previous step can be removed at this stage.

Table 24. Metathesis reaction on compound 358a.

[a] Reaction performed on pure starting material **358a**. [b] Reaction performed with starting material containing BHT (10 to 20%) with 0.5 mmol of **358a**. [c] Reaction performed with starting material containing BHT (10 to 20%) with 1.7 mmol of **358a**.

The molecular structure of **380** was ascertained by single-crystal X-ray diffraction. Spectroscopic data (<sup>1</sup>H and <sup>13</sup>C NMR, mass) were in full agreement with this structure.

Figure 19. Single crystal X-ray structure of 380.

The derivative **358c** was subjected to the same reaction conditions as described in Entry 3, Table 24. After 24 h, the reaction was stopped and analysed by <sup>1</sup>H NMR. Starting material **358c** represented more than 80% of the crude mixture (Entry 1, Table 25). Formation of at least two compounds was observed, but we were unable to determine the accurate ratio and to identify these products. Despite the low reactivity, an overview of the stability of the

compound **358c** was obtained. At a moderate temperature range (45-50 °C) under an inert atmosphere in presence of BHT, **358c** was stable and recovered. Thus, a reaction was performed in toluene at 100 °C for 66 h (Entry 2, Table 25). No starting material or identifiable products were found by crude analysis, *i.e.* NMR and TLC. <sup>11</sup>B NMR analysis showed that the major product was the formation of a boroxine-type compound with a chemical shift of  $\delta = 22.4$  ppm. This low reactivity is in agreement with previous observations.<sup>164</sup>

Table 25. Metathesis reaction on compound 358c.

Entry	<b>Reaction conditions</b>	358c Consumption
1 <sup>[a]</sup>	DCM, 45 °C, 24 h	< 20%
2 <sup>[a]</sup>	Toluene, 100 °C, 66 h	100 %

[a] Reaction performed with a starting material containing 16% of BHT.

The envne metathesis of **358d** was also tried based on the same reaction conditions in Entry 3, Table 24 in order to prepare the polyene **382**. No reaction occurred and the starting material was recovered after 24 h with 86% yield.

Scheme 107. Enyne metathesis on 358d.

A study still has to be conducted on substrates **358c** and **358d**, involving a screening of catalysts, and examination of the effect of concentration and temperature.

#### Mechanistic aspects

The ring closing metathesis on compound 358a led to the selective formation of the 1,3boronated diene 380, without traces of the 7-membered ring 381. Mechanistically, an intermolecular [2+2]-cycloaddition between the ruthenium complex and the allylic double bound took place to form the ruthenium cyclobutane intermediate 383 that can be likely due to steric hindrance. Retro-cycloaddition provided the active alkylidene specie 384 for the intramolecular [2+2]-cycloaddition. At this stage the ring formation may go through two different pathways: 1) The cycloaddition on the alkene in green on Scheme 108, to afford the intermediate 385 creating the oxazine 6-membered ring. Release of the alkylidene species would have allowed catalytic cycle to proceed and a new 1,3-boronated diene 380 to be formed; 2) The cycloaddition could have occured on the boron substituted alkene. In this pathway, the intermediate would afford the formation of a 7-membered ring skeleton with an exocylic double bond in green on 385'. The metathesis reaction is a catalytic cycle based on reversible steps. Therefore, some parameters have a major impact to drive the reaction towards the formation of the final product, in our case, the formation of volatile ethylene compared with a vinyl boronate. Secondly, the selectivity observed for this reaction can be explained by thermodynamically favoured formation of 6-membered rings compared to higher homologues. Lastly, skeleton 381 is a more constricted structure with a diene including an exocyclic alkene which may result from a higher energy barrier.

Scheme 108. Mechanism of the RCM to synthesise 380.

#### V.3.c. The arylnitroso Diels-Alder/ring contraction sequence

1,3-Boronated dienes have proved to provide pyrroles through a mechanism described in Chapter 2. Despite the fact that compound **380** showed higher strain due to the oxazine ring, it seemed reasonable to expect the same reactivity, even in low yield. Optimisation of the reaction using diene 241c showed that MeOH was the best solvent for pyrrole formation. However, for better solubility, we chose a mixture of DCM/MeOH (1/6) as solvent. To our delight, the reaction worked smoothly with nitrosobenzene 160a (2.5 eq.) to provide the desired compound with an excellent 96% yield in 24 h (Entry 1, Table 26). The formation of azoxybenzene 278 was also observed as by-product, but in small amounts. A small decrease in yield was, however, observed with 1.5 eq (89%) (Entry 2). Screening different arylnitroso compounds was performed, and fused, bicyclic oxazine-pyrroles were obtained in good to excellent yields (Entries 3, 6 and 7, Table 26). Electron-deficient arylnitroso derivatives 160b, 160g and 160h showed higher reactivity than the electron-rich arylnitroso 160d. Whereas reactions with 160b, 160g and 160h showed full conversion of the starting material after 24 h, a 47% conversion of **380** was observed by <sup>1</sup>H NMR analysis of the crude reaction mixture. Furthermore, a larger amount of azoxybenzene 258d was obtained. By reducing the rate of Diels-Alder/rearrangement process, the competition with the azoxybenzene formation became more problematic. As a result, with electron-donating substituent in the para-position of the aromatic ring, 2.5 eq. of arylnitroso 126 and an extended reaction time was necessary to observe full conversion of 380 (Entry 4). Even if the reactivity was decreased, the yield was not affected and product **386d** was isolated in 91%. If an ortho-substituted arylnitroso was used, a decrease of the reactivity was also observed. With 1.5 eq. of 160f, 26% conversion was observed after 72 h at r.t. If another 1.5 eq. was added the conversion reached 58% after 6 days. The reaction was then carried out with 3 eq. of 160f at reflux conditions and a full

conversion of **380** was observed after 66 h yielded product **386f** in 67% yield (Entry 5). The *ortho*-substitution decreased significantly the rate of the reaction, which can be explained by a steric hindrance effects.

 Table 26. Synthesis of fused oxazine-pyrrole bicycle synthesis.

R = H, Me, Br, Cl, OMe,  $CO_2Et$ 

The formation of fused oxazine-pyrrole bicycle synthesis proved to be very efficient (96%), even if one of the olefin was endocyclic (in red in Eq. 1 in Scheme 109), in comparison with the carbocyclic version (Eq. 2).

Scheme 109. Comparison on the reactivity between the heterocyclic diene 380 and carbocylic diene 241b.

A possible explanation could be found from the difference in the configuration of the cyclohexenyl ring. In some cases, heterocyclic compounds can adopt boat-like conformations which are formed initially through [4+2]-cycloadditions anyway, whereas the cyclohexene ring has a flatter structure.<sup>168</sup>

#### Mechanistic aspects

A mechanism explaining the formation of the fused oxazine-pyrrole derivative can be based on the mechanism described in Scheme 69. First, a regioselective arylnitroso Diels-Alder reaction with a 1,2-oxygen-boron related regioisomer (in red in Schme 110) reaction could take place to afford the bicyclic oxazine ring system **387**. No theoretical calculations have been made for this particular case, but according to previous results and calculations for the reference rearrangement process using 1,3-dienyl boronate, an *endo*-pathway might be preferred. Then, the consecutive boryl rearrangement leading to **388**, followed by the intramolecular aza-boryl to aldehyde addition to give **389**. Finally, the elimination step would provide the fused oxazine-pyrrole product **386**.

Scheme 110. Mechanism of the formation of the fused bicyclic oxazine-pyrrole product 386.

#### V.3.d. The Diels-Alder/allylboration sequence.

The Diels-Alder/allylboration sequence was also tried on compound **380**, with the optimised reaction conditions described in Entry 12, Table 20, with *N*-phenyl maleimide **2a** as dienophile and *p*-nitrobenzaldehyde **35**. The reaction was stopped after 48 h and checked by <sup>1</sup>H NMR. A 64% conversion of **380** was measured for formation of the cycloadduct **390**. However, no trace of any allylboration compound was observed. No allylation product was observed after 80 h of combined reaction time, and only the [4+2]-cycloadduct **390** was obtained, which was isolated in 38% yield with traces of a second adduct (around 8%) after silica gel chromatography (Scheme 111). Derivative **380** and cycloadduct **390** showed higher ring strain than **315** and **339a**, that could explain the decrease of reactivity, and moreover, avoided the allylboration occuring, as already observed previously.<sup>42</sup>

Scheme 111. Diels-Alder/allylboration sequence on 380.

An analysis of the coupling constant is in favor of an *endo* adduct by analogy with compound **339a**. Measured coupling constant for **390**,  $J_{\text{H1-H2}} = 5.3$  Hz, was in the same range as  $J_{\text{H1-H2}} = 5.8$  Hz for **339a**. In the case of the *exo* isomer **339a'** in Table 22,  $J_{\text{H1-H2}} = 2.2$  Hz was calculated.

Table 27. Comparison of coupling constant between 390 and 339a.

## VI. Summary

Compound **292** has proved to be a key intermediate for the synthesis of different structures, depending on the sequence employed. A one-pot Diels-Alder/allylboration cascade process has been developed to afford polycyclic products. The outcome of the reaction was directly related to the dienophile and the aldehyde used for the sequence. For the Diels-Alder reaction to proceed, a maleic structure was required, yielding stereoselectively the *endo*-isomer. Acetone, a more polar solvent, favoured the allylboration step, with the yield depending on the electronic properties of the arylaldehyde. Electron-poor substituted benzaldehydes exerted better reactivity. This process enabled the synthesis of highly functionalised products with control of four stereocenters. An interesting spirocyclic compound was obtained by using *trans*-cinnamaldehyde. Further tests, using other  $\alpha$ , $\beta$ -unsaturated aldehydes bearing electron-withdrawing groups need to be examined to see if the behaviour of the *trans*-cinnamaldehyde can be generalised. A class of novel oxazine-pyrrole fused bicylic compounds was also

synthesised based on an allylation/RCM/arylnitroso Diels-Alder/rearrangement process. After solving the problem of polymerisation of the allylation compound by adding a radical inhibitor, the synthesis of the oxazine-pyrrole was straightforward and products were isolated up to 48% overall yield. The same sequence using the acryloyl and the propargyl protected hydroxycarbamate did not show the desired reactivity. A more in depth study of the reaction conditions for the metathesis using these substrates is required. Finally, modification of the boron substituent on compound **292** showed reserved results. Whereas the synthesis trifluoroboronated variant worked perfectly, the synthesis and purification process of the BMIDA and the DEA derivatives still needs to be improved.

# Conclusions

## Perspectives

## I. Conclusions

The chemistry of 1,3-dienylboronate compounds with arylnitroso derivatives is driven by three major factors: the hybridisation of the boron unit; the substitution on the diene; and the solvent used for the reaction. The presence of an sp<sup>2</sup>-hybridised (Bpin) or a solvolysable sp<sup>3</sup>hybridised (BDEA or BF<sub>3</sub>K) borodiene led to the formation of the corresponding pyrrole. The yield of the reaction is dependent on the electronic properties and the position of the substituents on the diene. To favour the formation of the pyrrole, less electron-withdrawing boron and R<sup>2</sup> substituents, as well as low steric hindered R<sup>1</sup> and R<sup>2</sup> substituents were required. To isolate the oxazine derivatives resulting from a [4+2]-cycloaddition, stable sp<sup>3</sup>-hybridised boron moiety (BMIDA) is necessary. These cycloadducts were synthesised with a high regiocontrol toward the 1,2-boron-oxygen related adduct. The second isomer 1,3-boronoxygen related adduct was only observed if R<sup>2</sup> was a phenyl moiety. NMR studies on the two different boronated MIDA ester oxazines highlighted the possibility of selective deprotection of each regioisomer depending on the structure and the media used. Furthermore, it supported the theoretical calculations for the mechanism we proposed, based on an arylnitroso Diels-Alder/rearrangement/borate elimination cascade process.

The synthesis of nitrone derivatives bearing a pyrrole unit was also achieved from pinacol 1,3-dienylboronate variant in AcOEt or toluene with excess of arylnitroso species. First investigations to explain the outcome of the reaction have been performed. Taking advantage of the nitrone formation, a one-pot procedure nitrone/Diels-Alder sequence was used to provide highly functionalised oxazoline derivatives, albeit in modest yield.

These results are summarised in the Scheme below.

Secondly, we have examined the reactivity of 1,3-dienylboronate compounds towards carbonylnitroso derivatives. Three different scaffolds were formed according to the hybridation of the boron unit and the nature of the X substituent. The MIDA variant exerted the same regioselectivity as for arylnitroso species. Exclusive formation of the 1,2-boron-oxygen related adduct was observed in moderate yield. When the trifluoroborate was employed, pyrrole was synthesised in moderate yield following the mechanism previously proposed. The outcome of the reaction with the Bpin variant was directly related to the substituent X. With -NHR as substituent, the pyrrole was obtained in very low yield, whereas the -OR substitution led to the formation of the ene-compound in moderate yield. The ene-

intermediate has been further used in different multi-component sequences. First, a one-pot Diels-Alder/allylboration cascade reaction has been optimised to provide polycyclic compounds depending on the nature of both the dienophile and the aldehyde. Novel oxazine-pyrrole fused bicyclic compounds were obtained using metathesis/arylnitroso Diels-Alder/ring contraction sequence. Finally the same Diels-Alder/allylboration was applied on the 1,3-boronated diene oxazine ring. Only Diels-Alder compound was obtained, no allylboration being observed.

## **II.** Perspectives

This work has shown the synthetic potential of boronated dienes with nitroso derivatives. Concerning the use of arylnitroso derivatives, whereas the pyrrole formation has been rationalised by a mechanism supported by theoretical and experimental studies, the formation of the maleimide, and the nitrone derivatives are not, or have only partially, been explained. Further investigations need to be undertaken to determine the type of mechanism involved, and the influence of each parameter responsible for these differences in reactivity. Despite the synthesis of nitrone with high synthetic potential, only 1,3-dipolar cycloaddition using *N*-phenyl maleimide worked. Yields have to be improved and a diversification of the different partners should be performed to expand the structural diversity.

Related to the chemistry of carbonylnitroso derivatives, a highly interesting feature of this chemistry is the possibility to selectively synthesise the ene-adduct by using a strong electronwithdrawing enophile. A screening of possible enophiles has to be carried out to enlarge the range of molecules which can be synthesised. A preliminary study has been done in that sense, and ethyl glyoxylate exerted promising results. An asymmetric version of the enereaction could be envisaged. Further functionalisation using methodology developed for the nitroso chemistry could be used to synthesise polycyclic compounds incorporating other heterocycles (piperidine and tetrahydropyran for example).

Among the polycyclic compound synthesised within this work, the fused bicyclic oxazinepyrrole skeleton exerted an interesting structure for potential biologically active compounds. These compounds have been selected by Eli Lilly and Co. for screening. A library of molecules could be obtain by modifying the substituents:

- R substituent; CBz deprotection, followed by chemistry on the free nitrogen (*N*-alkylation for example)
- R<sup>1</sup> substituent; carbonylnitroso Diels-Alder/rearrangement process to provide carbonyl moiety as R<sup>1</sup>
- R<sup>2</sup> and R<sup>3</sup> substituents; electophilic substitution
- N-O cleavage

# Experimental

## Section

## **General experimental**

Reagents and solvents were used as received from the supplier, unless specified otherwise. When specified, dried solvents were used; THF and toluene were distilled over sodium, benzophenone and DCM over  $P_2O_5$ , or solvents were dried over activated molecular sieves 4 Å overnight.<sup>169</sup> Reactions were monitored by TLC analysis using silica gel 60  $F_{254}$  plates. Purifications on silica gel were carried out using silica gel 0.060–0.200 mm, 60 Å.

NMR spectra were recorded on spectrometer at 300, 400, 500 or 700 MHz for <sup>1</sup>H, 75 or 101 MHz for <sup>13</sup>C, and 96 MHz for <sup>11</sup>B. <sup>1</sup>H and <sup>13</sup>C NMR chemical shifts were referenced relative to Me<sub>4</sub>Si as internal reference and <sup>11</sup>B NMR chemical shifts to external BF<sub>3</sub>·OEt<sub>2</sub> (0.0 ppm). Deuterated chloroform CDCl<sub>3</sub>, DMSO- $d^6$  or  $d^6$ -acetone were used for NMR spectra. NMR data are reported as chemical shift (ppm), multiplicity (s = singlet, d = doublet, t = triplet, q = quartet, dd = doublet of doublet, ddd = doublet of doublet of doublet, dt = doublet of triplet, m = multiplet, b = broad), coupling constant *J* (Hz), and integration.

Low resolution mass spectra (LRMS) and high-resolution mass spectra (HMRS) were obtained using a Waters (UK) TQD mass spectrometer (low resolution ESI+), Waters (UK) Xevo QTOF mass spectrometer (low and high resolution ASAP+), Shimadzu QP2010-Ultra (low resolution EI) or a Waters (UK) LCT premier XE (high resolution ESI+) in Durham University, or using a Bruker MicrO-Tof-Q 2 or a Waters Q-Tof 2 at the CRMPO (Centre Régional de Mesures Physiques de l'Ouest, Rennes, France) using ESI or EI techniques. Melting points were measured using a Gallenkamp Variable Heater and reported in °C and are uncorrected.

Infrared spectra were measured on a Perkin Elmer<sup>©</sup> Spectrum Two IR Spectrometers and reported in cm<sup>-1</sup>.

Products **252**, **259**, **264**, **276**, **277i**, **277j** and **277k** were synthesised and characterised by a previous PhD student (Dr Fabien Tripoteau). These reactions were not repeated.

All boronated MIDA ester oxazines were purified by solid phase silica gel chromatography. The crude mixture was dissolved in acetone and silica added. Acetone was cautiously evaporated to obtain a dry crude mixture adsorbed on silica. The sample was then dropped on the column.

## **Diene syntheses**

### A. Enyne hydroboration

Enyne 238a.

To a solution of **237** (1.6 g, 10.4 mmol) in dry  $Et_3N$  (25 mL) was added CuI (20.0 mg, 0.10 mmol) and Pd(PPh<sub>3</sub>)<sub>2</sub>Cl<sub>2</sub> (146.1 mg, 0.21 mmol). The reaction mixture was flushed with argon for 5 min. Trimethylsilylacetylene **43** (2.20 mL, 15.6 mmol) was added and the reaction mixture was stirred overnight (18 h) at room temperature. Aqueous HCl (1 M, 5 mL) was added and the crude mixture was extracted with  $Et_2O$  (3x). The organic layer was washed with water (2x), the organic layer was dried over MgSO<sub>4</sub>, filtered and evaporated. The crude product was diluted with MeOH (5 mL) and K<sub>2</sub>CO<sub>3</sub> (2.87 g, 20.8 mmol) was added and the reaction mixture was stirred for 2 h. The MeOH was evaporated and the crude mixture was diluted in  $Et_2O$  (20 mL). The organic layer was washed with brine (2x) and with H<sub>2</sub>O (2x), dried over MgSO<sub>4</sub>, filtered and evaporated. The crude product was purified by silica gel chromatography to afford compound **238a** in *E/Z* ratio of (91/9) as yellow oil (947.0 mg, 66%).

<sup>1</sup>**H NMR (400 MHz, Chloroform-***d***, δ ppm**) 7.23 – 7.38 (m, 5H), 7.04 (d, *J* = 16.2 Hz, 1H), 6.11 (dd, *J* = 16.2, 2.4 Hz, 1H), 3.04 (d, *J* = 2.4 Hz, 1H).

<sup>13</sup>C NMR (101 MHz, Chloroform-*d*, δ ppm) 143.1, 135.9, 128.9, 128.7, 126.2, 107.1, 82.9, 79.2.

All analytical and spectroscopic properties were identical to those reported in the literature.<sup>170</sup>
#### A.1. General procedure for the catalytic hydroboration:

To a mixture of diene **238** (1 eq.) and Schwartz catalyst **240** (0.05 eq.) at 0 °C under an inert atmosphere, was added HBpin **239** (1.1 eq.) dropwise. After addition, the reaction mixture was warmed and stirred at r.t. for 24 h. The reaction mixture was carefully diluted with  $Et_2O$  and  $H_2O$ , and stirred for 20 min. The mixture was stirred for 20 min. The aqueous layer was extracted with  $Et_2O$  (3x). The combiend organic layer were then washed with brine (2x), then with  $H_2O$  (1x), and dried over MgSO<sub>4</sub>, filtered and evaporated. The crude product was purified by either silica gel chromatography or bulb-to-bulb distillation.

Boronated pinacol ester diene 241a.

The general procedure for the catalytic hydroboration with a mixture of diene **238a** (500 mg, 3.90 mmol), Schwartz catalyst **240** (50.3 mg, 0.19 mmol) and HBpin **239** (622  $\mu$ L, 4.29 mmol) afforded after silica gel chromatography, compound **241a** as an yellow oil (852.0 mg, 85%).

<sup>1</sup>**H NMR (300 MHz, Chloroform-***d***, δ ppm)** 7.47 – 7.40 (m, 2H), 7.38 – 7.24 (m, 3H), 7.19 (dd, *J* = 17.6, 10.2 Hz, 1H), 6.92 – 6.80 (dd, *J* = 15.6, 10.2 Hz 1H), 6.70 (d, *J* = 15.6 Hz, 1H), 5.68 (d, *J* = 17.6 Hz, 1H), 1.30 (s, 12H).

<sup>13</sup>C NMR (101 MHz, Chloroform-d, δ ppm) 149.8, 136.9, 136.2, 130.6, 128.7, 128.1, 126.8, 83.2, 24.8, C-B not visible.

All analytical and spectroscopic properties were identical to those reported in the literature.<sup>171</sup>

Boronated pinacol ester diene 241b.

The general procedure for the catalytic hydroboration with a mixture of diene **238b** (500 mg, 4.71 mmol), Schwartz catalyst **240** (60.7 mg, 0.24 mmol) and HBpin **239** (752  $\mu$ L, 5.18 mmol) afforded after silica gel chromatography, compound **241b** as an yellow oil (849.0 mg, 77%).

<sup>1</sup>H NMR (400 MHz, Chloroform-d, δ ppm) 7.02 (d, J = 18.3 Hz, 1H), 5.98 – 5.95 (m, 1H), 5.42 (dd, J = 18.3, 0.8 Hz, 1H), 2.21 – 2.08 (m, 4H), 1.72 – 1.55 (m, 4H), 1.27 (s, 12H).

All analytical and spectroscopic properties were identical to those reported in the literature.<sup>172</sup>

Boronated pinacol ester diene 241c.

The general procedure for the catalytic hydroboration with a mixture of diene **238c** (2 mL, 21.04 mmol), Schwartz catalyst **240** (271.0 mg, 1.05 mmol) and HBpin **239** (3.7 mL, 25.6 mmol) afforded after silica gel chromatography compound **241c** as a light yellow oil (3.59 g, 89%).

<sup>1</sup>**H NMR (400 MHz, Chloroform-***d***, δ ppm)** 7.09 (d, *J* = 18.2 Hz, 1H), 5.54 (dt, *J* = 18.2, 0.6 Hz, 1H), 5.14 (tt, *J* = 1.1, 0.6 Hz, 2H), 1.83 (t, *J* = 1.1 Hz, 3H), 1.27 (s, 12H).

<sup>13</sup>C NMR (101 MHz, Chloroform-*d*, δ ppm) 152.3, 143.1, 120.2, 116.7, 83.3, 24.9, 17.8.

All analytical and spectroscopic properties were identical to those reported in the literature.<sup>173</sup>

#### A.2. General procedure for the hydroboration using Ipc<sub>2</sub>BH:

# 1<sup>st</sup> step: Preparation of Ipc<sub>2</sub>BH 244:

A solution of pinene **242** (2 eq.) in dry THF was cooled at 0 °C under an argon atmosphere. BH<sub>3</sub>·SMe<sub>2</sub> **243** (1 eq.) was added and the reaction mixture was stirred at 0 °C for 15 min, then 2 h at r.t. Formation of Ipc<sub>2</sub>BH **244** as a white precipitate was observed.

# 2<sup>nd</sup> step: Hydroboration:

The solution of  $Ipc_2BH$  **244** was cooled to 0 °C again, and 2-methyl-but-1-en-3-yne **238c** (1 eq.) was added. After stirring at 0 °C during 30 min, the solution was stirred 6 h at r.t. Freshly ditillated acetaldehyde **246** (excess), was added to the solution at 0 °C, and the reaction mixture was stirred the time presented in the experimental procedure at r.t.. THF and excess of acetaldehyde were first distillated under inert atmosphere, then 1,3-dienylboronic ester intermediate **247** was distillated by bulb-to-bulb distillation. The 1,3-dienylboronic ester

intermediate **247** (1 eq.) was diluted in the solvent and at the temperature indicated in the experimental procedure.

#### Boronated MIDA ester diene 249.

1<sup>st</sup> step: Pinene 242 (2.5 mL, 15.8 mmol) and BH<sub>3</sub>·SMe<sub>2</sub> 243 (655 μL, 7.0 mmol) in THF (2.5 mL) provided Ipc<sub>2</sub>BH 244.

 $2^{nd}$  step: Addition of 2-methyl-but-1-en-3-yne 238c (655 µL, 7.0 mmol) followed by freshly ditillated acetaldehyde 246 (12 mL), afforded after bulb-to-bulb distillation intermediate 247 as a colourless oil (2.20 g, 13.1 mmol). The 1,3-dienylboronic ester intermediate 247 was diluted with a mixture of toluene/DMSO (15/1, 16 mL). MIDA 248 (1.73 g, 11.8 mmol) and phenothiazine (25 mg) as polymerisation inhibitor were added and the reaction mixture heated under an inert atmosphere at reflux for 2 h. The solution was cooled to r.t. and the white precipitate was filtered and washed with Et<sub>2</sub>O to provide diene MIDA ester 249 as a white solid (2.40 g, 63%). (Et<sub>2</sub>O/MeCN, 8/2 R<sub>f</sub> = 0.45).

**M.p.** = 155 °C.

#### Boronated pinacol ester acrolein 105.

1<sup>st</sup> step: Pinene 242 (11.3 mL, 70.5 mmol) and BH<sub>3</sub>SMe<sub>2</sub> 243 (3.3 mL, 35.5 mmol) in THF (11.5 mL) provided Ipc<sub>2</sub>BH 244.

 $2^{nd}$  step: Addition of alkyne 253 (5.1 mL, 35.5 mmol) was followed by freshly ditillated acetaldehyde 246 (20 mL). After removing THF and excess of acetaldehyde, H<sub>2</sub>O (5 mL) was added and the mixture stirred for 1.5 h at room temperature. Excess pinene was then removed using high vaccum and the crude mixture extracted with a mixture Et<sub>2</sub>O/AcOEt (1/1, 3x). The organic layer was dried over MgSO<sub>4</sub>, filtered and evaporated until precipitation started to be observed. Pentane (10 mL) was added and the mixture was stirred for 1 h. The solid was filtered and washed with pentane (2x) to afford boronic acid 254 as pale yellow powder (1.66 g, 47%). A solution of pinacol 255 (576.0 mg, 4.9 mmol) in a mixture of Et<sub>2</sub>O/MeOH (9/1, 8 mL) was added to boronic acid 254 (500.0 mg, 5.0 mmol). The reaction mixture was stirred overnight (16 h) and cyclohexane (20 mL) was added to the mixture. The organic layer was washed with brine (2x), then dried over MgSO<sub>4</sub>, filtered and evaporated. The crude product was purified by bulb-to-bulb distillation to afford compound 105 as a colorless oil (437.0 mg, 49%).

<sup>1</sup>**H NMR (400 MHz, Chloroform-***d***, δ ppm)** 9.60 (d, *J* = 7.5 Hz, 1H), 6.81 (dd, *J* = 18.1, 7.5 Hz, 1H), 6.65 (d, *J* = 18.1 Hz, 1H), 1.30 (s, 12H).

<sup>13</sup>C NMR (**75** MHz, Chloroform-*d*, δ ppm) 195.0, 147.7, 147.0, 84.4, 24.8.

# C. Coupling reaction of vinylboronic acid MIDA ester derivatives

# C.1. General procedure for the Suzuki-Miyaura cross-coupling:

# 1<sup>st</sup> step: Catalyst preparation:

SPhos (0.025 eq.) and  $Pd(OAc)_2$  (0.015 eq.) were stirred for 45 min at r.t. under an inert atmosphere in dry toluene.

# 2<sup>nd</sup> step: Cross-coupling reaction:

*Trans*-2-bromovinylboronic acid MIDA ester **267** (1 eq.), boronic acid **268a-c** (1.5 eq.) and KF (2 eq.) were suspended in dry toluene under an inert atmosphere. The catalsyt solution was added to the mixture and the reaction was stirred at r.t. overnight (18 h). The solvent was evaporated and the crude product was solubilised in acetone and filtered through a pad of celite/silica. The filtrate was evaporated to give the product.

#### Boronated MIDA ester diene 269a.

1<sup>st</sup> step: SPhos (12.0 mg, 0.029 mmol) and Pd(OAc)<sub>2</sub> (4.0 mg, 0.017 mmol) in dry toluene (2 mL) provided the catalyst solution.

2<sup>nd</sup> step: *Trans*-2-Bromovinylboronic acid MIDA ester 267 (300.0 mg, 1.15 mmol), *trans*-2-phenylvinylboronic acid 268a (255.0 mg, 1.72 mmol), KF (133.1 mg, 2.30 mmol) and the catalyst solution provided a full conversion of the starting material. The product 269a was isolated as a yellow solid (248.3 mg, 76%).

<sup>1</sup>**H NMR (400 MHz, Acetone-***d*<sub>6</sub>, δ **ppm**) 7.51 – 7.46 (m, 2H), 7.36 – 7.31 (m, 2H), 7.27 – 7.21 (m, 1H), 6.94 (ddd, *J* = 15.6, 10.3, 0.8 Hz, 1H), 6.75 (dd, *J* = 17.3, 10.3 Hz, 1H), 6.67 (d, *J* = 15.6 Hz, 1H), 5.84 (d, *J* = 17.3 Hz, 1H), 4.24 (d, *J* = 16.9 Hz, 2H), 4.06 (d, *J* = 16.9 Hz, 2H), 3.04 (s, 3H).

<sup>13</sup>C NMR (101 MHz, Acetone-*d*<sub>6</sub>, δ ppm) 169.1, 143.5, 138.2, 134.0, 131.9, 129.5, 128.5, 127.3, 62.3, 47.4, C-B not visible.

All analytical and spectroscopic properties were identical to those reported in the literature.<sup>122</sup>

Boronated MIDA ester diene 269b.

 $1^{st}$  step: SPhos (9.2 mg, 0.023 mmol) and Pd(OAc)<sub>2</sub> (3.0 mg, 0.014 mmol) in dry toluene (2 mL) provided the catalyst solution.

2<sup>nd</sup> step: *Trans*-2-bromovinylboronic acid MIDA ester 267 (236.0 mg, 0.90 mmol), 1phenylvinylboronic acid 268b (200.0 mg, 1.35 mmol), KF (105.1 mg, 1.80 mmol) and the catalyst solution provided a full conversion of the starting material. The product 269b was isolated as yellow solid (168.2 mg, 68%).

<sup>1</sup>**H** NMR (400 MHz, Acetone- $d_6$ ,  $\delta$  ppm) 7.41 – 7.27 (m, 5H), 6.87 (d, J = 17.8 Hz, 1H), 5.68 (d, J = 17.8 Hz, 1H), 5.22 (d, J = 1.9 Hz, 1H), 4.22 (d, J = 16.9 Hz, 2H), 4.06 (d, J = 16.9 Hz, 2H), 3.01 (s, 3H).

<sup>13</sup>C NMR (101 MHz, Acetone-*d*<sub>6</sub>, δ ppm) 169.0, 150.3, 144.2, 141.1, 129.1, 129.0, 128.3, 117.7, 62.5, 47.5, C-B not visible.

All analytical and spectroscopic properties were identical to those reported in the literature.<sup>122</sup>

Boronated MIDA ester diene 269c.

 $1^{st}$  step: SPhos (9.2 mg, 0.023 mmol) and Pd(OAc)<sub>2</sub> (3.0 mg, 0.014 mmol) in dry toluene (2 mL) provided the catalyst solution.

 $2^{nd}$  step: *Trans*-2-bromovinylboronic acid MIDA ester 267 (250.0 mg, 0.95 mmol), boronic acid 268c (183.0 mg, 1.43 mmol), KF (111.4 mg, 1.91 mmol) and the catalyst solution provided after 48 h a 63% conversion of the starting *trans*-2-bromovinylboronic acid MIDA ester 267. The crude was filtrated through celite and eluted with acetone (250 mL), evaporated and purified by silica gel chromatography using the solid sample method to afford two fractions. The first fraction was pure diene 269c obtained as a white solid (48 mg) and the second was as a mixture of diene 269c and starting material 367 (68/32, 115 mg). Total mass of desired diene 269c (126.2 mg, 50%).

# **M.p.** = 122 °C.

<sup>1</sup>**H NMR (400 MHz, Acetone-***d*<sub>6</sub>, δ **ppm**) 6.53 (dd, J = 17.5, 10.2 Hz, 1H, H<sub>7</sub>), 6.18 – 6.07 (m, 1H, H<sub>8</sub>), 5.81 – 5.72 (m, 1H, H<sub>9</sub>), 5.54 (d, J = 17.5 Hz, 1H, H<sub>6</sub>), 4.19 (d, J = 16.8 Hz, 2H, H<sub>2</sub> or H<sub>3</sub>), 4.01 (d, J = 16.8 Hz, 2H, H<sub>2</sub> or H<sub>3</sub>), 2.98 (s, 3H, H<sub>1</sub>), 2.13 – 2.07 (m, 2H, H<sub>10</sub>), 1.45 – 1.27 (m, 4H, H<sub>12</sub> and H<sub>11</sub>), 0.89 (t, J = 7.2 Hz, 3H, H<sub>13</sub>).

#### C.2. Stille cross-coupling:

#### Boronated MIDA ester diene 271.

*Trans*-2-bromovinylboronic acid MIDA ester **267** (262.0 mg, 1.00 mmol),  $Pd_2dba_3$  (37.1 mg, 0.04 mmol), and  $Fur_3P$  (21.0 mg, 0.09 mmol) were dissolved under an inert atmosphere in dry DMF (8 mL). Tributylvinyltin **270** (346 mL, 1.15 mmol) was added and the reaction mixture stirred at 45 °C overnight (18 h). The DMF was removed by bulb-to-bulb distillation to afford a sticky black solid. The crude product was dissolved in AcOEt, filtered through a pad of Celite and rinsed with AcOEt several times. The filtrate was evaporated providing a biphasic (oil/liquid) mixture. The solvent liquid layer was separated by decantating and the residual oil was rinsed with Et<sub>2</sub>O and separated again, by decantating until a colorless Et<sub>2</sub>O washing solution was obtained. The remaining oil/solid was stirred overnight (16 h) in a mixture

DCM/Et<sub>2</sub>O (1/7, 24 mL). The resulting precipitate was filtered and washed with Et<sub>2</sub>O (3x) to afford compound **271** as a light brown solid (140.2 mg, 67%).

<sup>1</sup>**H NMR (400 MHz, Acetonitrile-***d*<sub>3</sub>, δ **ppm**) 6.56 (dd, *J* = 17.5, 10.5 Hz, 1H), 6.43 (dtd, *J* = 17.0, 10.0, 0.5 Hz, 1H), 5.66 (dd, *J* = 17.5, 0.5 Hz, 1H), 5.28 (ddt, *J* = 17.0, 2.0, 0.5 Hz, 1H), 5.14 (ddt, *J* = 10.0, 2.0, 0.5 Hz, 1H), 3.96 (d, *J* = 17.0 Hz, 2H), 3.79 (d, *J* = 17.0 Hz, 2H), 2.76 (s, 3H).

<sup>13</sup>C NMR (101 MHz, Acetonitrile-*d*<sub>3</sub>, δ ppm) 169.5, 144.3, 119.0, 62.3, 47.6.

All analytical and spectroscopic properties were identical to those reported in the literature.<sup>122</sup>

#### Vinyl boronated MIDA ester 274.

To a solution of vinylboronic MIDA ester **272** (2.0 g, 10.9 mmol) in dry DCM (10 mL) at 0 °C was added neat bromine **273** (1 mL, 19.1 mmol) drpwise. The reaction mixture was stirred at r.t. for 1.5 h. The excess of bromine and DCM were carefully removed by evaporation under a fume hood. DCM (10 mL) was added and re-evaporated (azeotropes bromine). The crude product was dissolved in MeCN (8 mL) and DBU (4.2 g, 27.3 mmol) was added in one portion at r.t. The reaction mixture was stirred for 1.5 h, aqueous HCl (1 M, 8 mL) was added and the mixture stirred for 15 min. The crude product was extracted with a mixture of AcOEt/acetone (3/1, 3x), and the organic layer was washed with a mixture of sodium metabisulfite/brine (3/2, 2x), then brine. The organic layer was dried over MgSO<sub>4</sub>, filtered and evaporated until the formation of a precipitate was observed. Et<sub>2</sub>O (80 mL) was added and the mixture was stirred overnight. The precipitate was filtered and washed with Et<sub>2</sub>O (2x) to afford compound **274** as white powder (1.46 g, 51%).

<sup>1</sup>**H NMR (400 MHz, Acetone-***d*<sub>6</sub>, δ **ppm**) 6.39 (d, *J* = 1.4 Hz, 1H), 6.19 (bs, 1H), 4.37 (d, *J* = 17.0 Hz, 2H), 4.16 (d, *J* = 17.0 Hz, 2H), 3.16 (s, 3H).

<sup>13</sup>C NMR (101 MHz, Acetone- $d_6$ , δ ppm) 168.4, 129.6, 63.5, 47.3, C-B not visible. All analytical and spectroscopic properties were identical to those reported in the literature.<sup>123</sup>

Boronated MIDA ester diene 275.

 $1^{st}$  step: dpph (139.0 mg, 0.31 mmol) and Pd<sub>2</sub>dba<sub>3</sub> (70.1 mg, 0.077 mmol) were stirred for 30 min at r.t. under an inert atmosphere in dry THF.

 $2^{nd}$  step: Compound 274 (400.0 mg, 1.53 mmol), 1-phenylvinylboronic acid 268b (340.2 mg, 2.29 mmol) and Ag<sub>2</sub>CO<sub>3</sub> (1.69 g, 6.12 mmol) were suspended in dry THF (8 mL) under an inert atmosphere. The catalyst solution was added to the reaction and the mixture was stirred at 40 °C for 24 h. The crude product was purified filtered through a pad of Celite and washed with MeCN (200 mL). The filtrate was evaporated and purified by silica gel chromatography using the solid sample method to provide a mixture of diene 275 and starting material 274 (70/30, 343 mg). Mass total of desired diene 275 (240.1 mg, 55%).

<sup>1</sup>**H NMR (400 MHz, Acetone-***d*<sub>6</sub>, δ **ppm**) 7.42 – 7.21 (m, 5H), 5.74 (d, *J* = 3.7 Hz, 1H), 5.64 – 5.61 (m, 1H), 5.27 (d, *J* = 1.8 Hz, 1H), 5.25 (d, *J* = 1.8 Hz, 1H), 4.21 – 4.15 (d, *J* = 16.9 Hz, 2H), 3.92 (d, *J* = 16.9 Hz, 2H), 3.08 (s, 3H).

# B. Reaction of tetracoordinated 1-borodienes with arylnitroso compounds

General procedure for the oxazine synthesis:

To a solution of diene (1 eq) (MIDA ester **249**, **269a-c** and **271**) in AcOEt was added the arylnitroso **160** (2.5 eq). The reaction mixture was stirred at room temperature or under reflux. The solvent was evaporated and the crude product purified by silica gel chromatography.

Oxazine 280a.

To a suspension of diene **249** (20 mg, 0.09 mmol) in AcOEt (1 mL) was added nitrosobenzene **160a** (15 mg, 0.13 mmol). The reaction mixture was stirred at r.t. overnight. The solvent was evaporated and the residue was purified by silica gel chromatography (eluent, Et<sub>2</sub>O/acetonitrile 8/2,  $R_f = 0.5$ ) to afford oxazine **280a** as a white solid (19 mg, 64%).

### **M.p.** = 211 °C.

#### **Oxazines 285 + 285'**.

To a suspension of diene **269a** (50 mg, 0.18 mmol) in AcOEt (2 mL), was added nitrosobenzene **160a** (38 mg, 0.35 mmol). The reaction mixture was stirred at reflux for 24 h. The solvent was evaporated and the crude product purified by solid phase silica gel chromatography (eluent, Et<sub>2</sub>O/MeCN, 8/2,  $R_f = 0.4$ ) to afford **285 + 285'** as a mixture (40/60, 62.8 mg, 89%). The mixture of isomers was dissolved in the minimum amount of CHCl<sub>3</sub>, and left overnight in a fridge at + 5 °C to form a white precipiate. The precipitate was filtered, washed with Et<sub>2</sub>O and recrystallized in MeOH to afford pure isomer **285'** as white crystals (29.3 mg, 42%). The filtrate was evaporated and diluted in CHCl<sub>3</sub> (1 mL). Aqueous HCl (1M) (0.5 mL) was added and heterogeneous mixture was vigorously stirred for 24 h to decompose the residual isomer **285'**. The organic phase was separated, dried over MgSO<sub>4</sub>, filtered and concentrated under vacuum. After purification by silica gel chromatography (eluent, Et<sub>2</sub>O/MeCN, 8/2,  $R_f = 0.4$ ), isomer **285** was obtained as a pale yellow solid (21.3 mg, 30%).

Crystal structure data for 285':

A suitable crystal was selected and measured on a APEXII, Bruker-AXS diffractometer. The crystal was kept at 120 K during data collection. The structure was solved by direct methods using the *SIR97* program,<sup>181</sup> and then refined with full-matrix least-square methods based on  $F^2$  (*SHELXL-97*)<sup>182</sup> with the aid of the *WINGX* program.<sup>183</sup> All non-hydrogen atoms were refined with anisotropic atomic displacement parameters. H atoms were finally included in their calculated positions. A final refinement on  $F^2$  with 4726 unique intensities and 284 parameters converged at  $\omega R(F^2) = 0.0955$  (R(F) = 0.0426) for 3438 observed reflections with  $I > 2\sigma(I)$ .

# C. Mechanistic aspects of the reaction 1-borodienes with arylnitroso compounds

#### C.1. Conversion of 285 to pyrrole 277l under basic conditions:

Oxazine **285** (6.0 mg, 0.015 mmol) was dissolved in acetone- $d_6$  (0.4 mL). NaOD (1 M in water, 15  $\mu$ L, 0.015 mmol) was then added and the reaction was directly followed by <sup>1</sup>H and

<sup>11</sup>B NMR. After one night, a 32% conversion was observed with no further evolution if the reaction was left longer at r.t. NaOD (1 M, 30  $\mu$ L, 0.030 mmol) was finally added to observe complete consumption of the starting oxazine **285**, followed by DCl (1 M in D<sub>2</sub>O, 15  $\mu$ L, 0.015 mmol). After 15 min, a full conversion into the corresponding pyrrole was observed. The reaction mixture was poured into DCM (2 mL), and H<sub>2</sub>O (1 mL) was added. The aqueous layer was extracted with DCM (3 x) and the organic layer was dried over MgSO<sub>4</sub>, filtered over a pad of silica gel and eluted with DCM to give pyrrole **2771** (2.8 mg, 85%).

#### C.2. Conversion of 285' to 2-phenylfuran 294 under acidic conditions:

Oxazine **285'** (6.8 mg, 0.017 mmol) was dissolved in acetone- $d^6$  (0.4 mL). DCl in D<sub>2</sub>O (1 M, 18  $\mu$ L, 0.018 mmol). After full conversion of the starting oxazine, reaction mixture was poured into DCM (1 mL). NaOH (1 M, 0.2 mL) was added. The aqueous layer was extracted with DCM (3 x), dried over MgSO<sub>4</sub>, filtered and purified over a pad of silica and eluted with DCM to give furan **294** (2.4 mg, quantitative).

<sup>1</sup>**H NMR (400 MHz, Chloroform-***d***, δ ppm)** 7.71 – 7.66 (m, 2H), 7.48 (dd, *J* = 1.8, 0.7 Hz, 1H), 7.42 – 7.36 (m, 2H), 7.30 – 7.24 (m, 1H), 6.66 (dd, *J* = 3.4, 0.8 Hz, 1H), 6.48 (dd, *J* = 3.4, 1.8 Hz, 1H).

<sup>13</sup>C NMR (101 MHz, Chloroform-*d*, δ ppm) 154.1, 142.2, 131.0, 128.8, 127.5, 123.9, 111.8, 105.1.

All analytical and spectroscopic properties were identical to those reported in the literature.<sup>184</sup>

#### C.3. Isolation of by-product boronated MIDA ester aniline 299:

Oxazine **285'** (25.2 mg, 0.064 mmol) was dissolved in acetone- $d_6$  (0.7 mL). DCl (1 M in D<sub>2</sub>O, 64 µL, 0.064 mmol) was then added and the reaction was followed by <sup>1</sup>H and <sup>11</sup>B NMR. After full conversion of the starting oxazine, the reaction mixture was extracted with DCM (3 x), dried over MgSO<sub>4</sub>, filtered and concentrated. The crude yellow solid was suspended in CHCl<sub>3</sub> (0.5 mL) and filtered. The resulting solid was washed with CHCl<sub>3</sub> (3 x) to afford **299** as a white solid (4 mg, 25%).

<sup>1</sup>**H NMR (400 MHz, Acetone-** $d_6$ , **\delta ppm**) 7.07 (m, 2H, H<sub>8</sub>), 6.85 (m, 2H, H<sub>7</sub>), 6.62 (m, 1H, H<sub>9</sub>), 4.74 (bs, 1H, NH), 4.25 (d, J = 17.2 Hz, 2H, H<sub>2</sub> or H<sub>3</sub>), 4.09 (d, J = 17.2 Hz, 2H, H<sub>2</sub> or H<sub>3</sub>), 3.01 (s, 3H, H<sub>1</sub>).

<sup>13</sup>C NMR (101 MHz, Acetone-*d*<sub>6</sub>, δ ppm) 167.6 (C<sub>4</sub> and C<sub>5</sub>), 147.2 (C<sub>6</sub>), 129.0 (C<sub>8</sub>), 117.4 (C<sub>9</sub>), 116.2 (C<sub>7</sub>), 62.1 (C<sub>2</sub> and C<sub>3</sub>), 45.8 (C<sub>1</sub>).

<sup>11</sup>**B NMR (96 MHz, Acetone-***d*<sub>6</sub>, δ ppm) 9.9.

**LRMS (ESI+)** 271.1 (36%)  $[M+Na]^+$ , 249.1 (100%)  $[M+H]^+$ , 188.1 (11%), 156.0 (12%). **HRMS (ESI+)** calcd. for  $[M+H]^+(C_{11}H_{14}N_2O_4^{-11}B)$ : 249.1047 found: 249.1042.

#### D. Transformations of borono-1,6-dihydro-1,2-oxazine derivatives

Oxazine 301.

To a suspension of diene **277** (229 mg, 0.80 mmol) in AcOEt (10 mL), was added nitrosobenzene **160a** (221 mg, 2.06 mmol). The reaction mixture was stirred at 50 °C for 22 h. The solvent was evaporated and the crude product purified by solid phase silica gel chromatography (eluent, Et<sub>2</sub>O/MeCN, 8/2,  $R_f = 0.4$ ) to afford **301** as a white solid (229 mg, 73%).

**M.p.** = 153 °C.

<sup>1</sup>**H NMR (400 MHz, Acetone-***d*<sub>6</sub>, δ **ppm**) 7.40 – 7.25 (m, 7H, H<sub>15</sub>, H<sub>16</sub>, H<sub>17</sub> and H<sub>12</sub>), 7.17 (m, 2H, H<sub>11</sub>), 6.94 (m, 1H, H<sub>13</sub>), 4.67 (m, 2H, H<sub>6</sub>), 3.97 (m, 2H, H<sub>9</sub>), 3.94 (d, *J* = 16.8 Hz, 2H, H<sub>2</sub> or H<sub>3</sub>), 3.43 (d, *J* = 16.8 Hz, 2H, H<sub>2</sub> or H<sub>3</sub>), 3.07 (s, 3H, H<sub>1</sub>).

<sup>13</sup>C NMR (101 MHz, Acetone-d<sub>6</sub>, δ ppm) 168.2 (C<sub>4</sub> and C<sub>5</sub>), 151.5 (C<sub>10</sub>), 144.4 (C<sub>14</sub>), 141.9 (C<sub>8</sub>), 129.7 (C<sub>12</sub>, C<sub>15</sub> or C<sub>16</sub>), 129.5 (C<sub>12</sub>, C<sub>15</sub> or C<sub>16</sub>), 129.4 (C<sub>12</sub>, C<sub>15</sub> or C<sub>16</sub>), 128.2 (C<sub>17</sub>), 122.5 (C<sub>13</sub>), 116.2 (C<sub>11</sub>), 72.2 (C<sub>6</sub>), 63.0 (C<sub>2</sub> and C<sub>3</sub>), 58.3 (C<sub>9</sub>), 47.3 (C<sub>1</sub>), B-C not visible.

<sup>11</sup>**B NMR (96 MHz, Acetone-***d*<sub>6</sub>, δ ppm) 10.4.

**LRMS (ESI+)** 393.1 (100%)  $[M+H]^+$ , 281.7 (75%), 264.2 (52%), 220.1 (71%). **HRMS (ESI+)** calcd. for  $[M+H]^+(C_{21}H_{22}N_2O_5^{-11}B)$ : 393.1618 found: 393.1622.

#### Oxazine 303.

In a flask under an inert atmosphere was added oxazine **301** (41 mg, 0.10 mmol), Pd(OAc)<sub>2</sub> (1.2 mg, 0.0053 mmol), SPhos (4.3 mg, 0.010 mmol) and 2-bromotoluene **302** (14  $\mu$ L, 0.11 mmol) in dioxane (2 mL). An aqueous solution of K<sub>3</sub>PO<sub>4</sub> (3 M, 190 mL, 0.57 mmol) previously degassed with argon for 15 min was then added. The orange reaction mixture was stirred at 60 °C overnight. Et<sub>2</sub>O (5 mL) and NaOH (1 M, 5 mL) were added in the reaction mixture, then aqueous layer was extracted with Et<sub>2</sub>O (3 x) and the organic layer was dried over MgSO<sub>4</sub>, filtered and concentrated under vacuum. The crude compound was purified by silica gel chromatography (eluent, hexane/AcOEt 95/5, R<sub>f</sub> = 0.4). to afford **303** as a white solid (27.1 mg, 71%).

#### **M.p.** = 161 °C.

<sup>1</sup>**H NMR (400 MHz, Chloroform-***d***, δ ppm)** 7.40 – 6.83 (m, 14H, HAr), 4.58 (s, 2H, H<sub>6</sub>), 4.12 (s, 2H, H<sub>9</sub>), 2.00 (s, 3H, H<sub>24</sub>).

<sup>13</sup>C NMR (101 MHz, Chloroform-*d*, δ ppm) 150.2 (C<sub>10</sub>), 138.9 (C), 137.1 (C), 136.1 (C), 134.1 (C<sub>18</sub>), 131.0 (C<sub>7</sub>), 130.3 (C), 130.0 (C), 129.1 (C<sub>12</sub>, C<sub>15</sub> or C<sub>16</sub>), 128.2 (C<sub>12</sub>, C<sub>15</sub> or C<sub>16</sub>), 128.1 (C<sub>12</sub>, C<sub>15</sub> or C<sub>16</sub>), 127.6 (C), 127.2 (C), 125.8 (C), 122.8 (C<sub>13</sub>), 116.2 (C<sub>11</sub>), 72.0 (C<sub>6</sub>), 55.4 (C<sub>9</sub>), 19.7 (C<sub>24</sub>).

**LRMS (ESI+)** 328.2 (36%) [M+H]<sup>+</sup>.

**HRMS (ESI+)** calcd. for  $[M+H]^+(C_{23}H_{22}NO)$ : 328.1689 found: 328.1701.

## E. The one-pot nitrone formation/1,3-dipolar cycloaddition sequence

#### Nitrone 304g.

Diene **241c** (127.0 mg, 0.65 mmol) and 4-nitrosobenzoate **160g** (372.7 mg, 2.08 mmol) were dissolved in AcOEt (3 mL). The reaction mixture was stirred at r.t. for 1.5 h, then hexane (10 mL) was added to the crude mixture. The resulting solid was filtered and washed with hexane (2 x) to afford compound **304g** as an orange solid (142.7 mg, 54%).

**M.p.** = 165 °C.

<sup>1</sup>**H** NMR (400 MHz, Chloroform-*d*,  $\delta$  ppm) 8.99 (t, *J* = 1.9 Hz, 1H, H<sub>12</sub>), 8.18 – 8.13 (m, 4H, H<sub>5</sub> and H<sub>15</sub>), 8.08 (d, *J* = 0.6 Hz, 1H, H<sub>11</sub>), 7.93 – 7.88 (m, 2H, H<sub>14</sub>), 7.59 – 7.53 (m, 2H, H<sub>6</sub>), 7.24 (dd, *J* = 3.2, 2.3 Hz, 1H, H<sub>8</sub>), 6.70 (dd, *J* = 3.2, 1.5 Hz, 1H, H<sub>9</sub>), 4.41 (q, *J* = 7.1 Hz, 2H, H<sub>18</sub> or H<sub>2</sub>), 4.40 (q, *J* = 7.1 Hz, 2H, H<sub>18</sub> or H<sub>2</sub>), 1.42 (t, *J* = 7.1, 3H, H<sub>1</sub> or H<sub>19</sub>), 1.41 (t, *J* = 7.1, 3H, H<sub>1</sub> or H<sub>19</sub>).

**LRMS (ESI+)** 407.0 (27%) [M+H]<sup>+</sup>, 391.3 (100%) [M-O]<sup>+</sup>.

**HRMS** (ESI+) calcd. for  $[M+H]^+(C_{23}H_{23}N_2O_5)$ : 407.1607 found: 407.1602.

Single crystal X-ray structure data for **304g**:

A suitable crystal was selected and measured on a D8V\_Mo diffractometer. The crystal was kept at 120 K during data collection. Using Olex2,<sup>185</sup> the structure was solved with the ShelXS structure solution program<sup>182</sup> using Direct Methods and refined with the ShelXL refinement package using Least Squares minimisation.<sup>182</sup>

### E.1. General procedure for the <sup>1</sup>H NMR monitoring:

Diene **241c** (1 eq.) and arylnitroso **160** (2.5 eq.) were dissolved in AcOEt. The reaction mixture was stirred at r.t. and monitored by <sup>1</sup>H NMR analysis. A sample was taken by syringe after 24 h, and the reaction was stopped after 48 h.

## E.2 General procedure for the one-pot procedure nitrone formation/1,3-dipolar cycloaddition:

To arylnitroso compound **160** (3.2 eq) was added a solution of diene **241c** in dry toluene. The reaction mixture was stirred at r.t. for 1.5 h. *N*-phenyl maleimide **2a** (1.1 eq) was added and

the reaction mixture flushed with argon for 10 min. The reaction mixture was heated at 90 °C for 16 h under an inert atmosphere. The crude mixture was cooled to r.t., then toluene was evaporated and the crude product purified by silica gel chromatography.

#### Oxazolines 305a and 305a'.

To nitrosobenzene **160a** (153.6 mg, 1.43 mmol) was added a solution of diene **241c** (87.4 mg, 0.45 mmol) in dry toluene (1.5 mL). The reaction mixture was stirred at r.t. for 1.5 h. *N*-phenyl maleimide **2a** (85.8 mg, 0.49 mmol) was added and the reaction mixture was flushed with argon for 10 min. The reaction mixture was heated at 90 °C for 16 h under an inert atmosphere. The crude mixture was cooled to r.t., then toluene was evaporated and the crude product purified by silica gel chromatography (eluent, hexane/AcOEt, 1/1,  $R_{f305a} = 0.75$ ,  $R_{f305a'} = 0.70$ ) to afford isomer **305a** as a yellow-orange solid (29.0 mg, 15%), and isomer **305a'** as a yellow-orange solid (19.1 mg, 10%).

#### **305a: M.p.** = 87 °C.

Single crystal X-ray structure data for **305a'**:

A suitable crystal was selected and measured on a D8V\_Mo diffractometer. The crystal was kept at 120 K during data collection. Using Olex2,<sup>185</sup> the structure was solved with the ShelXS structure solution program<sup>182</sup> using Direct Methods and refined with the ShelXL refinement package using Least Squares minimisation.<sup>182</sup>

#### Oxazolines 305g and 305g'.

To ethyl 4-nitrosobenzoate **160g** (262.4 mg, 1.46 mmol) was added a solution of diene **241c** (91.7 mg, 0.472 mmol) in dry toluene (1.6 mL). The reaction mixture was stirred at r.t. for 1.5 h. *N*-phenyl maleimide **2a** (90,0 mg, 0.520 mmol) was added and the reaction mixture was flushed with argon for 10 min. The reaction mixture was heated at 90 °C for 16 h under an inert atmosphere. The crude mixture was cooled to r.t., then toluene was evaporated and the crude product purified by silica gel chromatography (eluent, hexane/AcOEt, 1/1,  $R_{f305g} = 0.65$ ,  $R_{f305g'} = 0.60$ ) to afford isomer **305g** as an orange solid (38.3 mg, 14%) and isomer **305g'** as a pale orange solid (70,0 mg, 26%).

#### **305g: M.p.** = 97 °C.

Oxazoline 305b.

To ethyl 4-chloronitrosobenzene **160b** (195.1 mg, 1.38 mmol) was added a solution of diene **241c** (83.6 mg, 0.43 mmol) in dry toluene (1.5 mL). The reaction mixture was stirred r.t. for 1.5 h. *N*-phenyl maleimide **2a** (82,0 mg, 0.47 mmol) was added and the reaction mixture was flushed with argon for 10 min. The reaction mixture was heated at 90 °C for 16 h under an inert atmosphere. The crude mixture was cooled to r.t., then toluene was evaporated and the crude product purified by silica gel chromatography (eluent, hexane/AcOEt, 1/1,  $R_f = 0.75$ ) to afford isomer **305b** as an orange solid (57.2 mg, 26%).

**M.p.** = 98 °C

**HRMS** (**ESI**+) calcd. for  $[M+H]^+(C_{27}H_{20}Cl_2N_3O_3)$ : 504.0882 found: 504.0883.

Single crystal X-ray structure data for **305b**:

A suitable crystal was selected and measured on a D8V\_Mo diffractometer. The crystal was kept at 120 K during data collection. Using Olex2,<sup>185</sup> the structure was solved with the ShelXS structure solution program<sup>182</sup> using Direct Methods and refined with the ShelXL refinement package using Least Squares minimisation.<sup>182</sup>

Table XX. Crystal data and structure refinen	nent
--	------

Empirical formula	$C_{29}H_{23}Cl_2N_3O_4$
Formula weight	548.40
Temperature/K	120
Crystal system	monoclinic
Space group	$P2_1/c$
a/Å	14.6746(8)
b/Å	6.4961(4)
c/Å	26.7054(14)
α/°	90
β/°	91.634(3)
γ/°	90
Volume/Å <sup>3</sup>	2544.7(2)
Z	4
$\rho_{calc}g/cm^3$	1.431
$\mu/mm^{-1}$	2.647
F(000)	1136.0
Crystal size/mm <sup>3</sup>	0.3  imes 0.04  imes 0.03
Radiation	$CuK\alpha$ ( $\lambda = 1.54184$ )
$2\Theta$ range for data collection/	6.026 to 136.312
Index ranges	$\textbf{-}17 \leq h \leq 16,  \textbf{-}7 \leq k \leq 7,  \textbf{-}30 \leq l \leq 32$
Reflections collected	17303
Independent reflections	4446 [ $R_{int} = 0.0443$ , $R_{sigma} = 0.0483$ ]
Data/restraints/parameters	4446/0/317
Goodness-of-fit on F <sup>2</sup>	1.058

Final R indexes [I>= $2\sigma$ (I)]	$R_1 = 0.0655, wR_2 = 0.1344$
Final R indexes [all data]	$R_1 = 0.0818$ , $wR_2 = 0.1412$
Largest diff. peak/hole / e Å <sup>-3</sup>	0.80/-0.66

**Table XXI.** Fractional Atomic Coordinates (×10<sup>4</sup>) and Equivalent Isotropic Displacement Parameters (Å<sup>2</sup>×10<sup>3</sup>).  $U_{eq}$  is defined as 1/3 of of the trace of the orthogonalised  $U_{IJ}$  tensor.

Oxazoline 305h.

To ethyl 4-bromonitrosobenzene **160h** (255.1 mg, 1.37 mmol) was added a solution of diene **241c** (83.2 mg, 0.43 mmol) in dry toluene (1.5 mL). The reaction mixture was stirred at r.t. for 1.5 h. *N*-phenyl maleimide **2a** (81,7 mg, 0.47 mmol) was added and the reaction mixture was flushed with argon for 10 min. The reaction mixture was heated at 90 °C for 16 h under an inert atmosphere. The crude mixture was cooled to r.t., then toluene was evaporated and the crude product purified by silica gel chromatography (eluent, hexane/AcOEt, 1/1,  $R_f = 0.75$ ) to afford isomer **305h** as an orange solid (59.1 mg, 23%).

**M.p.** = 109 °C.

<sup>1</sup>**H** NMR (400 MHz, Chloroform-*d*,  $\delta$  ppm) 7.56 – 7.52 (m, 2H, H<sub>Ph</sub>), 7.44 – 7.36 (m, 3H, H<sub>Ph</sub>), 7.36 – 7.31 (m, 2H, H<sub>Ph</sub>), 7.25 – 7.20 (m, 2H, H<sub>Ph</sub>), 7.09 (ddd, *J* = 2.4, 1.7, 0.6 Hz, 1H, H<sub>12</sub>), 7.04 – 6.98 (m, 3H, H<sub>13</sub> and H<sub>Ph</sub>), 6.82 – 6.76 (m, 2H, H<sub>Ph</sub>), 6.36 (dd, *J* = 3.0, 1.8 Hz, 1H, H<sub>11</sub>), 5.62 (s, 1H, H<sub>9</sub>), 5.18 (dd, *J* = 7.5, 0.6 Hz, 1H, H<sub>7</sub>), 4.02 (dd, *J* = 7.5, 0.9 Hz, 1H, H<sub>8</sub>).

<sup>13</sup>C NMR (101 MHz, Chloroform-*d*, δ ppm) 174.2 (C<sub>6</sub>), 172.9 (C<sub>5</sub>), 147.5 (C<sub>21</sub>), 139.3 (C<sub>14</sub>), 132.8 (C<sub>Ph</sub>), 132.1 (C<sub>Ph</sub>), 131.0 (C<sub>Ph</sub>), 129.3 (C<sub>Ph</sub>), 129.2 (C<sub>Ph</sub>), 126.2 (C<sub>Ph</sub>), 123.5 (C<sub>10</sub>), 122.1 (C<sub>Ph</sub>), 120.4 (C<sub>13</sub>), 119.4 (C<sub>Ph</sub>), 117.7 (C<sub>12</sub>), 117. 1 (C<sub>Ph</sub>), 115.7 (C<sub>Ph</sub>), 109.7 (C<sub>11</sub>), 77.0 (C<sub>7</sub>), 65.0 (C<sub>9</sub>), 56.8 (C<sub>8</sub>).

**HRMS** (**ESI**+) calcd. for  $[M+H]^+(C_{27}H_{20}Br_2N_3O_3)$ : 591.9871 found: 591.9861.

#### Oxazolines 305f and 305f'.

To 2-nitrosotoluene **160f** (156.6 mg, 1.25 mmol) was added a solution of diene **241c** (78.4 mg, 0.40 mmol) in dry toluene (1.5 mL). The reaction mixture was stirred at r.t. for 1.5 h. *N*-phenyl maleimide **2a** (76.9 mg, 0.44 mmol) was added and the reaction mixture was flushed with argon for 10 min. The reaction mixture was heated at 90 °C for 16 h under an inert atmosphere. The crude mixture was cooled to r.t., then toluene was evaporated and the crude product purified by silica gel chromatography (eluent, hexane/AcOEt, 1/1,  $R_{f305f} = 0.75$ ,  $R_{f305f} = 0.70$ ) to afford isomer **305f** as a white solid (23.1 mg, 12%). The isomer **305f** was not isolated.

#### **305f: M.p.** = 179 °C.

<sup>1</sup>**H** NMR (700 MHz, Chloroform-*d*, δ ppm) 7.52 – 7.49 (m, 2H, H<sub>Ph</sub>), 7.45 – 7.42 (m, 1H, H<sub>Ph</sub>), 7.35 – 7.32 (m, 2H, H<sub>Ph</sub>), 7.26 – 7.18 (m, 3H, H<sub>Ph</sub>), 7.09 – 7.05 (m, 3H, H<sub>Ph</sub>), 6.98 – 6.92 (m, 2H, H<sub>Ph</sub>), 6.61 (t, J = 2.5 Hz, 1H, H<sub>12</sub>), 6.36 (t, J = 2.0 Hz, 1H, H<sub>13</sub>), 6.10 (dd, J = 2.8, 1.8 Hz, 1H, H<sub>11</sub>), 5.25 (d, J = 7.4 Hz, 1H, H<sub>7</sub>), 5.18 (s, 1H, H<sub>9</sub>), 4.11 (dd, J = 7.4, 1.1 Hz, 1H, H<sub>8</sub>), 2.26 (s, 3H, H<sub>27</sub>), 1.92 (s, 3H, H<sub>20</sub>).

Single crystal X-ray structure data for **305f**:

A suitable crystal was selected and measured on a D8V\_Mo diffractometer. The crystal was kept at 120 K during data collection. Using Olex2,185 the structure was solved with the ShelXS structure solution program<sup>182</sup> using Direct Methods and refined with the ShelXL refinement package using Least Squares minimisation.<sup>182</sup>

E.3. General procedure for the screening of the dipolarophile for the [3+2]-cycloaddition:

Diene **241c** (1 eq.) and 4-nitrosobenzoate **160g** (3.2 eq.) were dissolved in AcOEt. The reaction mixture was stirred at r.t. for 1.5 h. The dipolarophile (1.1 eq.) was added and the reaction mixture stirred under reflux for 22 h. The crude reaction mixture was evaporated and purified by silica gel chromatography.

#### Pyrrole 306g.

Diene **241c** (50.0 mg, 0.24 mmol) and 4-nitrosobenzoate **160g** (138.3 mg, 0.76 mmol) were dissolved in AcOEt (1.2 mL). The reaction mixture was stirred at r.t. for 1.5 h. Diethyl azodicarboxylate **307** (45  $\mu$ L, 0.28 mmol) was added and the reaction mixture stirred under reflux for 22 h. The crude reaction mixture was evaporated and purified by silica gel chromatography (eluent, hexane/AcOEt, 1/1, R<sub>f</sub> = 0.65) to afford **306g** as a yellow-orange solid (19.2 mg, 33%).

**M.p.** = 94 - 95 °C.

<sup>1</sup>**H NMR (400 MHz, Chloroform-***d***, δ ppm)** 9.88 (d, *J* = 0.7 Hz, 1H, H<sub>12</sub>), 8.20 – 8.14 (m, 2H, H<sub>5</sub>), 7.74 (dd, *J* = 2.2, 1.6 Hz, 1H, H<sub>11</sub>), 7.52 – 7.47 (m, 2H, H<sub>6</sub>), 7.17 (ddd, J = 3.0, 2.1, 0.7 Hz, 1H), 6.84 (dd, *J* = 3.1, 1.6 Hz, 1H), 4.41 (q, *J* = 7.1 Hz, 2H, H<sub>2</sub>), 1.42 (t, J = 7.1 Hz, 3H, H<sub>1</sub>).

Single crystal X-ray structure data for **306g**:

A suitable crystal was selected and measured on a D8V\_Mo diffractometer. The crystal was kept at 120 K during data collection. Using Olex2,<sup>185</sup> the structure was solved with the ShelXS structure solution program<sup>182</sup> using Direct Methods and refined with the ShelXL refinement package using Least Squares minimisation.<sup>182</sup>

#### E.4. Procedures for the study of the mechanistic aspects:

Pyrrole **277g** (47.0 mg, 0.20 mmol) and 4-nitrosobenzoate **160g** (77.2 mg, 0.45 mmol) were dissolved in AcOEt (1 mL). The reaction mixture was stirred at r.t. A sample was taken by syringe after 1.5 h and the reaction stopped after 24 h. The crude reaction mixture was evaporated, and no purification was performed.

Diene **241c** (1 eq.), 4-nitrosobenzoate **160g** (3.2 eq.) and TEMPO **314** (0.1 or 1 eq.) were dissolved in AcOEt. The reaction mixture was stirred at r.t. for 1.5 h. The solvent was evaporated and the crude reaction mixture analysed by <sup>1</sup>H NMR. No purification was performed.

To a solution of 4-nitrosobenzoate **160g** (3.2 eq.) in AcOEt under an inert atmosphere was added a solution of diene **241c** (1 eq.) in AcOEt. The reaction was stirred at r.t. for 1.5 h under an inert atmosphere. The solvent was evaporated and the crude reaction mixture analysed by <sup>1</sup>H NMR. No purification was performed.

Compound **315** (50.0 mg, 0.14 mmol) and 4-nitrosobenzoate **160g** (55.0 mg, 0.31 mmol) were dissolved in AcOEt (0.7 mL). The reaction mixture was stirred r.t. A sample was taken by syringe after 1.5 h and the reaction stopped after 24 h. The crude reaction mixture was evaporated, and no purification was performed.

#### Boronated dienes and carbonylnitroso compounds

A. Reaction of 1-dienylboronate pinacolate esters with carbonylnitroso compounds

#### Procedure using Bu<sub>4</sub>NIO<sub>4</sub>:

A solution of diene **241c** (37.5 mg, 0.19 mmol) and nitroso precursor **318a** (32.3 mg, 0.19 mmol) in DCM (0.5 mL) was cooled to -5 °C. A DCM solution (2 mL) of Bu<sub>4</sub>NIO<sub>4</sub> (83.8 mg 0.19 mmol) was added dropwise. The reaction mixture was stirred at -5 °C for 2 h. The crude mixture was washed with a saturated solution of Na<sub>2</sub>S<sub>2</sub>O<sub>5</sub> (2 x), saturated solution of NaHCO<sub>3</sub> (2 x), water (1 x) and finally brine (1 x). The organic layer was dried over MgSO<sub>4</sub>, filtered and evaporated. The crude product was analysed by <sup>1</sup>H NMR, (no purification was performed).

#### Procedure using Rose Bengal:

To a solution of Rose Bengal (4.6 mg, 0.0045 mmol) in MeCN (1 mL), was added pyridine (26  $\mu$ L, 6.20x10<sup>-4</sup> mol.L<sup>-1</sup> in MeCN). Nitroso precursor **318a** and diene **241c** (87.0 mg, 0.45 mmol) were then added successively. The reaction mixture was stirred at 35 °C (heating from the light) for 22 h under irradiation from a light bulb (40W).

#### Procedure using aerobic copper method:

A solution of copper source (0.2 eq.) and pyridine (0.05 eq.) was stirred at r.t. in THF for 5 min. To the solution was added diene **241c** (1 eq.) and carbonylnitroso precursor **318a** (1.5 eq.) and THF. The reaction mixture was stirred at r.t. until TLC showed full completion of the diene. The solvent was evaporated and the crude reaction product was purified by silica gel chromatography.

#### Carbonylnitroso ene-product 315.

A solution of CuCl (4.2 mg, 0.043 mmol) and pyridine (18  $\mu$ L, 6.19x10<sup>-4</sup> mol.L<sup>-1</sup> in THF) was prepared in THF (1 mL). After 5 min, diene **241c** (82.0 mg, 0.42 mmol), carbonyl nitroso precursor **318a** (106.0 mg, 0.63 mmol) and THF (1 mL) were added. The reaction mixture was stirred between 10 and 17 °C (cryostat) for 28 h. The solvent was evaporated, and the crude reaction product was purified by silica gel chromatography (eluent, hexane/AcOEt, 7/3,  $R_f = 0.55$ ) to afford compound **315** as a white solid (100.0 mg, 66%).

**M.p.** = 98 °C.

<sup>1</sup>**H NMR (400 MHz, Chloroform-***d***, δ ppm)** 7.36 (m, 5H, H<sub>11</sub>, H<sub>12</sub> and H<sub>13</sub>), 7.06 (d, *J* = 18.6 Hz, 1H, H<sub>4</sub>), 5.66 (d, *J* = 18.6 Hz, 1H, H<sub>3</sub>), 5.39 (s, 1H, H<sub>6</sub>), 5.34 (d, *J* = 1.0 Hz, 1H, H<sub>6</sub>), 5.20 (s, 2H, H<sub>9</sub>), 4.36 (s, 2H, H<sub>7</sub>), 1.28 (s, 12H, H<sub>1</sub>).

<sup>13</sup>C NMR (101 MHz Chloroform-*d*, δ ppm) 157.4 (C<sub>8</sub>), 149.2 (C<sub>4</sub>), 140.7 (C<sub>5</sub>), 135.9 (C<sub>10</sub>), 128.7 (C<sub>12</sub>), 128.4 (C<sub>13</sub>), 128.3 (C<sub>11</sub>), 121.0 (C<sub>6</sub>), 117.6 (C<sub>3</sub>), 83.5 (C<sub>2</sub>), 68.3 (C<sub>9</sub>), 51.6 (C<sub>7</sub>), 24.9 (C<sub>1</sub>).

<sup>11</sup>B NMR (96 MHz, Chloroform-*d*, δ ppm) 30.1.

**IR** (neat, υ) 3263, 1700, 1605, 1353, 1244, 1101, 1001, 907, 846, 756, 700, 590 cm<sup>-1</sup>. **LRMS** (ESI+) 360.2 [M+H]<sup>+</sup>, 315.6 (59%), 283.3 (22%). **HRMS** (ESI) calcd. for [M+H]<sup>+</sup>(C<sub>19</sub>H<sub>27</sub>NO<sub>5</sub><sup>11</sup>B): 360.1982 found: 360.1992.

Pyrrole 321.

Oxidation using aerobic copper method was followed using CuCl (9.1 mg, 0.092 mmol) and pyridine (39  $\mu$ L, 6.19x10<sup>-4</sup> mol.L<sup>-1</sup> in THF) in THF (1 mL). After 5 min, diene **241c** (80.0 mg, 0.46 mmol), carbonyl nitroso precursor **318b** (105.5 mg, 0.69 mmol) and THF (1 mL) were added. The reaction mixture was stirred at r.t. for 48 h. The crude reaction mixture was filtered over a pad of celite and washed with acetone (150 mL). The solvent was evaporated and the crude product was purified by silica gel chromatography (eluent, hexane/AcOEt, 7/3,  $R_f = 0.60$ ). to afford pyrrole **321** as a yellow solid (14.8 mg, 16%).

**M.p.** = 120 °C.

### B. Reaction of tetracoordinated 1-borodienes with carboylnitroso

compounds

#### B.1. Reaction using BMIDA diene 249:

Oxazine 322a.

#### Procedure using aerobic copper method:

CuCl (8.9 mg, 0.090 mmol) and pyridine (36  $\mu$ L, 6.19x10<sup>-4</sup> mol.L<sup>-1</sup> in THF) in THF (1 mL). After 5 min, diene **249** (100.0 mg, 0.45 mmol), carbonyl nitroso precursor **318a** (113.5 mg, 0.67 mmol) and THF (1 mL) were added. The reaction mixture was stirred at r.t. for 9 days. The solvent was evaporated and the crude product was purified by solid phase silica gel chromatography (eluent, Et<sub>2</sub>O/MeCN, 8/2, R<sub>f</sub> = 0.55) to afford oxazine **322a** as a white solid (125.4 mg, 72%).

#### Procedure using Bu<sub>4</sub>NIO<sub>4</sub>:

A solution of diene **249** (40 mg, 0.18 mmol) and nitroso precursor **318a** (37.4 mg, 0.22 mmol) in DCM (0.5 mL) was cooled to -5 °C. A DCM solution (2 mL) of Bu<sub>4</sub>NIO<sub>4</sub> (97.1 mg 0.22 mmol) was added dropwise. The reaction mixture was stirred at - 5 °C for 2 h. The crude was washed with a saturated solution of Na<sub>2</sub>S<sub>2</sub>O<sub>5</sub> (2 x), a saturated solution of NaHCO<sub>3</sub> (2 x), water (1 x) and finally brine (1 x). The organic layer was dried over MgSO<sub>4</sub>, filtered and evaporated. The crude product was purified by solid phase silica gel chromatography (eluent, Et<sub>2</sub>O/MeCN, 8/2, R<sub>f</sub> = 0.55) to afford oxazine **322a** as a white solid (26.0 mg, 37%).

**M.p.** = 185 °C.

<sup>1</sup>**H NMR (400 MHz, Acetone-***d*<sub>6</sub>,  $\delta$  **ppm**) 7.45 – 7.31 (m, 5H, H<sub>14</sub>, H<sub>15</sub> and H<sub>16</sub>), 5.64 (m, 1H, H<sub>7</sub>), 5.21 – 5.11 (m, 2H, H<sub>12</sub>), 4.40 (bs, 1H, H<sub>6</sub>), 4.30 (d, *J* = 17.2, 1H, H<sub>2</sub> or H<sub>3</sub>), 4.17 (d, *J* = 16.4, 1H, H<sub>2</sub> or H<sub>3</sub>), 4.16 – 4.11 (m, 1H, H<sub>10</sub>), 4.03 (d, *J* = 17.2, 1H, H<sub>2</sub> or H<sub>3</sub>) 3.86 (d, *J* = 16.4, 1H, H<sub>2</sub> or H<sub>3</sub>), 3.87 – 3.80 (m, 2H, H<sub>10</sub>), 3.20 (s, 3H, H<sub>1</sub>), 1.74 (dq, *J* = 2.4, 1.1 Hz, 3H, H<sub>9</sub>).

<sup>13</sup>C NMR (101 MHz, Acetone-*d*<sub>6</sub>, δ ppm) 169.1 (C<sub>4</sub> or C<sub>5</sub>), 168.0 (C<sub>4</sub> or C<sub>5</sub>), 156.3 (C<sub>11</sub>), 137.4 (C<sub>13</sub>), 129.4 (C<sub>15</sub>), 129.2 (C<sub>16</sub>), 129.1 (C<sub>14</sub>), 128.8 (C<sub>8</sub>), 120.9 (C<sub>7</sub>), 68.2 (C<sub>12</sub>), 63.1 (C<sub>2</sub> or C<sub>3</sub>), 63.0 (C<sub>2</sub> or C<sub>3</sub>), 49.1 (C<sub>10</sub>), 46.5 (C<sub>1</sub>), 20.1 (C<sub>9</sub>), B-C not visible.

<sup>11</sup>B NMR (96 MHz, Acetone-*d*<sub>6</sub>, δ ppm) 9.7.

**LRMS (ESI+)** 389.1 [M+H]<sup>+</sup>, 345.1 (43%), 172.1 (75%).

#### B.2. Reaction using BF<sub>3</sub>K diene 276:

Pyrrole 320.

Oxidation using aerobic copper method was followed using CuCl (9.1 mg, 0.092 mmol) and pyridine (39  $\mu$ L, 6.19x10<sup>-4</sup> mol.L<sup>-1</sup> in THF) in THF (1 mL). After 5 min, diene **276** (80.0 mg, 0.46 mmol), carbonyl nitroso precursor **318a** (115.3 mg, 0.69 mmol) and THF (1 mL) were added. The reaction mixture was stirred at r.t. for 22 h. The crude reaction mixture was filtered over a pad of celite and washed with acetone (150 mL). The solvent was evaporated and the crude product was purified by silica gel chromatography (eluent hexane/AcOEt, 7/3,  $R_f = 0.85$ ) to afford pyrrole **320** as a yellow oil (48.2 mg, 48%).

<sup>1</sup>**H NMR (400 MHz, Chloroform-***d***, δ ppm)** 7.45 – 7.35 (m, 5H, H<sub>9</sub>, H<sub>10</sub> and H<sub>11</sub>), 7.21 (t, *J* = 2.8 Hz, 1H, H<sub>4</sub>), 7.06 – 7.02 (m, 1H, H<sub>5</sub>), 6.09 (ddd, *J* = 3.2, 1.7, 0.6 Hz, 1H, H<sub>3</sub>), 5.35 (s, 2H, H<sub>7</sub>), 2.06 (dd, *J* = 1.2, 0.6 Hz, 3H, H<sub>1</sub>).

<sup>13</sup>C NMR (101 MHz, Chloroform-*d*, δ ppm) 150.4 (C<sub>6</sub>), 135.2 (C<sub>8</sub>), 128.8 (C<sub>9</sub> or C<sub>10</sub>), 128.5 (C<sub>9</sub> or C<sub>10</sub>), 123.4 (C<sub>2</sub>), 120.3 (C<sub>4</sub>), 117.4 (C<sub>5</sub>), 114.9 (C<sub>3</sub>), 68.8 (C<sub>7</sub>), 12.0 (C<sub>1</sub>).

**IR** (neat, υ) 1739, 1491, 1456, 1406, 1338, 1241, 1222, 1117, 1068, 971, 767, 696, 616 cm<sup>-1</sup>. **LRMS** (**ESI**+) 216.1 (71%) [M+H]<sup>+</sup>, 172.4 (100%).

**HRMS** (**ESI**+) calcd. for  $[M+H]^+(C_{13}H_{14}NO_2)$ : 216.1025 found: 216.1021.

Pyrrole 321.

Oxidation using aerobic copper method was followed using CuCl (9.1 mg, 0.092 mmol) and pyridine (39  $\mu$ L, 6.19x10<sup>-4</sup> mol.L<sup>-1</sup> in THF) in THF (1 mL). After 5 min, diene **250** (80.0 mg, 0.46 mmol), carbonyl nitroso precursor **318b** (105.5 mg, 0.69 mmol) and THF (1 mL) were added. The reaction mixture was stirred at r.t. for 20 h. The crude reaction mixture was filtered over a pad of celite and washed with acetone (150 mL). The solvent was evaporated and the crude product was purified by silica gel chromatography (eluent, hexane/AcOEt, 7/3,  $R_f = 0.60$ ). to afford pyrrole **321** as a yellow solid (49.1 mg, 53%).

For charactierisation, refer to section A.

#### The ene-adduct as key intermediate in cascade reactions

#### A. The Diels-Alder/allyboration sequence

#### A.1. General procedure for the Diels-Alder step:

To a solution of **315** in the solvent (DCM or toluene) was added the dienophile (1.1 eq). The reaction mixture was stirred at the temperature indicated in the work procedure. The crude reaction mixture was evaporated and the crude product purified by silica gel chromatography.

Diels-Alder cycloadduct 339a.

Compound **315** (54.0 mg, 0.15 mmol) and *N*-phenyl maleimide **2a** (28.6 mg, 0.17 mmol) were stirred in DCM (2 mL) at r.t. for 18 h. The crude was purified by silica gel chromatography (eluent, hexane/EtOAc, 1/1,  $R_f = 0.60$ ) to afford compound **339a** as a white solid (67.1 mg, 84%).

**M.p.** =  $89 - 90^{\circ}$ C.

<sup>1</sup>**H** NMR (600 MHz, Chloroform-*d*, δ ppm) 7.41– 7.37 (m, 2H, H<sub>18</sub>), 7.36 – 7.28 (m, 6H, H<sub>1</sub>, H<sub>2</sub>, H<sub>3</sub> and H<sub>19</sub>), 7.23 – 7.19 (m, 2H, H<sub>17</sub>), 6.82 (bs, 1H, OH), 6.07 (dt, J = 4.9, 1.6 Hz, 1H, H<sub>9</sub>), 5.15 (s, 2H, H<sub>5</sub>), 4.22 (d, J = 15.4 Hz, 1H, H<sub>7</sub>), 4.07 (d, J = 15.4 Hz, 1H, H<sub>7</sub>), 3.42 (ddt, J = 9.6, 6.5, 1.7 Hz, 1H, H<sub>13</sub>), 3.25 (ddt, J = 11.7, 6.5, 3.0 Hz, 1H, H<sub>12</sub>), 2.71 – 2.65 (m, 1H, H<sub>10</sub>), 2.30 (dd, J = 15.4, 7.7 Hz, 1H, H<sub>10</sub>), 2.11 – 2.07 (m, 1H, H<sub>11</sub>), 1.28 – 1.24 (m, 12H, H<sub>21</sub>).

<sup>13</sup>C NMR (101 MHz, Chloroform-*d*, δ ppm) 180.1 (C<sub>14</sub>), 179.0 (C<sub>15</sub>), 157.4 (C<sub>6</sub>), 136.0 (C<sub>4</sub>), 135.3 (C<sub>8</sub>), 132.1 (C<sub>16</sub>), 129.1 (C<sub>18</sub>), 128.6 (C<sub>3</sub> or C<sub>2</sub>), 128.3 (C<sub>19</sub> or C<sub>1</sub>), 128.2 (C<sub>3</sub> or C<sub>2</sub>), 127.0 (C<sub>19</sub> or C<sub>1</sub>), 126.7 (C<sub>17</sub>), 84.2 (C<sub>20</sub>), 68.2 (C<sub>5</sub>), 55.2 (C<sub>7</sub>), 42.0 (C<sub>13</sub>), 40.4 (C<sub>12</sub>), 25.9 (C<sub>10</sub>), 25.0 (C<sub>21</sub>), 24.8 (C<sub>21</sub>), 21.8 (C<sub>11</sub>).

<sup>11</sup>B NMR (96 MHz, Chloroform-d, δ ppm) 32.7.

**IR** (neat, υ) 3316, 1706, 1704, 1700, 1381, 1329, 1167, 1140, 1098, 853, 738, 693, 623 cm<sup>-1</sup>. **LRMS** (ESI+) 533.1 (100%) [M+H]<sup>+</sup>, 489.2 (98%).

**HRMS** (ESI+) calcd. for  $[M+H]^+(C_{29}H_{34}^{-10}BN_2O_7)$ : 532.2495 found: 532.2505.

Reaction using **2b**, **23**, **12** and **341** were performed at r.t. in DCM or at 90°C in toluene following the general procedure. No products were isolated.

#### A.2. General procedure for the Lewis acid catalysed Diels-Alder reaction:

In a oven-dried flask were solubilised compound **315** or compound **342** (1 eq.), freshly ground maleic anhydride (1.1 eq.) and the catalyst (0.1 eq.) in dry DCM under inert atmosphere. The reaction mixture was stirred at r.t. for 48 h. The crude reaction mixture was

washed with  $H_2O(3 x)$ . The aquous layer was extracted with DCM (2 x). The organic layer was dried over MgSO<sub>4</sub>, filtered and evaporated.

#### A.3. Calculations for the determination of the stereochemistry of 339a:

Conformational searches were carried out using Spartan '10.<sup>186</sup> Each structure was drawn and subjected to a full conformational search, using the Monte-Carlo algorithm with 500 conformations examined, and semi-empirical (AM1) energy minimisations to give the predictions of the 10 lowest energy conformations. Dihedral angles generated from the conformational searches were used to calculate coupling constants, using the MestReJ software.<sup>187</sup>

## A.4. General procedure for the optimisation of the one-pot Diels-Alder/allylboration sequence:

To a solution of **315** [X] in the solvent, were added *N*-phenyl maleimide **2a** (x eq) and pnitrobenzaldehyde **35** (x eq). The reaction mixture was stirred at the temperature presented in Table 20. The reaction was stirred from 48 hours to 1 week and monitored by <sup>1</sup>H NMR analysis. Reaction with [**315**] = 0.17 and 0.1 M were directly performed in NMR tube. Reaction with [**315**] = 1.00 M were performed in a hemolysis tube and sample were taken and diluted for NMR measurement.

A.5. General procedure using the optimised reaction conditions with substituted arylaldehydes and  $\alpha$ ,  $\beta$  unsaturated aldehydes:

To a solution of **315** [1 M] in acetone, were added the dienophile (1.1 eq) and the aldehyde (2.1 eq). The reaction mixture was stirred at 50 °C for 48 h. The solvent was evaporated and the crude product was purified by silica gel chromatography.

Polycylic product 340a.

Compound **315** (61.8 mg, 0.17 mmol), *N*-phenyl maleimide **2a** (32.8 mg, 0.19 mmol) and 4nitrobenzaldehyde **35** (54.6 mg, 0.36 mmol) were stirred in acetone (170  $\mu$ L) at 50 °C for 48 h. The crude was purified by silica gel chromatography (eluent, hexane/EtOAc, 1/1, R<sub>f</sub> = 0.40) to afford compound **340a** as a pale yellow solid (46.0 mg, 48%). **M.p.** = 127 °C (changed in state but not liquid), 158 °C.

<sup>1</sup>**H NMR** (**400 MHz**, **Chloroform**-*d*, δ **ppm**) 8.19 (bs, 1H, N-OH), 8.09 – 8.07 (m, 2H, H<sub>19</sub>) 7.44 – 7.31 (m, 10H, H<sub>Ar</sub>), 7.14 – 7.09 (m, 2H, H<sub>18</sub>), 6.19 (d, J = 10.3 Hz, 1H, H<sub>11</sub>), 6.07 (dd, J = 10.3, 2.6 Hz, 1H, H<sub>9</sub>), 5.23 – 5.19 (m, 2H, H<sub>5</sub>), 4.66 (s, 1H, H<sub>16</sub>), 4.08 – 4.06 (m, 1H, H<sub>7</sub>), 3.45 (m, 2H, H<sub>12</sub> and H<sub>13</sub>), 3.34 (d, J = 15.5 Hz, 1H, H<sub>7</sub>), 2.37 – 2.26 (m, 2H, H<sub>10</sub>).

Single crystal X-ray structure for **350**:

A suitable crystal obtained in DCM was selected and measured on a D8V\_Mo diffractometer. The crystal was kept at 120 K during data collection. Using Olex2,<sup>185</sup> the structure was solved with the ShelXS structure solution program,<sup>182</sup> using Direct Methods and refined with the ShelXL refinement package using Least Squares minimisation.<sup>182</sup>

#### **B.** Modification of the boron substituent

#### B.1. Trifluoroboronated salt 356a synthesis:

A solution of diene **315** (209 mg, 0.58 mmol) in MeOH (2 mL) was cooled to 0 °C. An aqueous solution of KHF<sub>2</sub> **146** (137 mg, 1.75 mmol, in 4 mL) was added to the reaction mixture. The reaction was allowed to reach r.t., and stirred overnight. The crude was evaporated to dryness. The residue was dissolved in acetone and the remaining salt was filtered. The salt was washed with acetone and the filtrate was evaporated. The white solid was resolubilised in the minimum amount of acetone. The solution was stirred vigorously and Et<sub>2</sub>O was added to precipitate the afford compound **356a** as a white solid (170.0 mg, 86%).

**M.p.** =  $123 \degree C$  (decomposition).

<sup>1</sup>**H NMR (400 MHz, Acetone-***d*<sub>6</sub>, δ **ppm**) 8.47 (bs, 1H, NH), 7.43 – 7.27 (m, 5H, H<sub>9</sub>, H<sub>10</sub> and H<sub>11</sub>), 6.38 (d, *J* = 18.5 Hz, 1H, H<sub>2</sub>), 5.80 (dq, *J* = 18.5, 3.5 Hz, 1H, H<sub>1</sub>), 5.15 (s, 2H, H<sub>4</sub>), 4.89 (s, 2H, H<sub>7</sub>), 4.31 (t, *J* = 1.3 Hz, 2H, H<sub>5</sub>).

**HRMS (ESI+)** calcd. for (C<sub>13</sub>H<sub>14</sub><sup>10</sup>BNO<sub>3</sub>F<sub>3</sub>): 299.1055 found: 299.1046.

#### **B.2.** Boronated MIDA ester derivative synthesis:

To a solution of **315** (50.0 mg, 0.14 mmol) in a mixture of toluene/DMSO (15/1 : 3 mL), were added MIDA **248** (18.4 mg, 0.12 mmol) and phenothiazine (2 mg) as polymerisation inhibitor. The reaction mixture was heated under inert atmosphere in reflux conditions for 4 h. The solution was cooled to r.t. and Et<sub>2</sub>O (10 mL) was added. The reaction mixture was stirred overnight. The white precipitate was filtered and washed with Et<sub>2</sub>O to provide starting MIDA ester **248** as a white solid (quantitative). The filtrate was evaporated and a mixture of starting **315**, pinacol **255**, and another boron species were obtained.

#### **B.3.** Boronated DEA ester derivative synthesis:

A solution of diethanolamine **250** (80.2 mg, 0.76 mmol) and **315** (54.8 mg, 0.15 mmol) in DCM (1 mL) was evaporated to dryness. The crude reaction mixture was then distillated by bulb to bulb distillation at 80 °C for 2 h, then at 120 °C for 3 h. The crude reaction mixture was cooled to r.t., then Et<sub>2</sub>O (10 mL) was added and the reaction mixture was stirred overnight. The white precipitate was filtered and washed with Et<sub>2</sub>O (2 x). <sup>1</sup>H and <sup>11</sup>B NMR showed a mixture of two species.

# C. The metathesis/arylnitroso Diels-Alder/ring contraction sequence

#### C.1. General procedure for the Synthesis of the O-substituted hydroxycarbamates:

A solution of diene **315** (1 eq) in DCM was cooled to 0 °C. Organohalide **357** (1.2 eq.) and base (1.2 eq.) were added successively at 0 °C. The mixture was stirred at 0 °C for 10 min, then at r.t. for 16 h. BHT was added and the crude mixture was evaporated. The crude was diluted in the minimum amount of DCM. The crude was filtered over a pad of silica and eluted with a mixture hexane/AcOEt (9/1) containing BHT. The filtrate was evaporated.

Allyl-protecttd ene-product 358a.

General procedure was followed using diene **315** (719 mg, 2.00 mmol), allylbromide **357a** (208  $\mu$ L, 2.40 mmol) and DBU (359  $\mu$ L, 2.40 mmol) in DCM (17 mL). The crude was filtered over a pad of silica (hexane/AcOEt, 7/3, R<sub>f</sub> = 0.80) and eluted with a mixture hexane/AcOEt (9/1, 555 mL) containing BHT (18 mg). The filtrate was evaporated to afford a mixture of compound **358a**/BHT (88/12, <sup>1</sup>H NMR measurement, 768 mg, 85%).

<sup>1</sup>**H NMR (400 MHz, Chloroform-***d***, δ ppm)** 7.42 – 7.29 (m, 5H, H<sub>11</sub>, H<sub>12</sub> and H<sub>13</sub>), 7.07 (d, *J* = 18.6 Hz, 1H, H<sub>4</sub>), 5.90 (ddt, *J* = 16.9, 10.3, 6.4 Hz, 1H, H<sub>15</sub>), 5.66 (d, *J* = 18.6 Hz, 1H, H<sub>3</sub>), 5.39 (s, 1H, H<sub>6</sub>), 5.34 (d, *J* = 1.1 Hz, 1H, H<sub>6</sub>), 5.30 – 5.21 (m, 2H, H<sub>16</sub>), 5.23 (s, 2H, H<sub>9</sub>), 4.33 – 4.30 (m, 2H, H<sub>14</sub>), 4.32 (s, 2H, H<sub>7</sub>), 1.28 (s, 12H, H<sub>1</sub>).

#### C.2. Protection of the hydroxycarbamate with the BF<sub>3</sub>K variant:

#### Pathway 1:

A solution of diene **356a** (0.30 mg, 0.074 mmol) in acetone (1 mL) was cooled to 0 °C. Allylbromide **357a** (8  $\mu$ L, 0.089 mmol) and DBU (14  $\mu$ L, 0.089 mmol) were added successively at 0 °C. The mixture was stirred at 0 °C for 10 min, then at r.t. for 16 h. The reaction mixture was evaporated.

#### Pathway 2:

A solution of diene **315** (57.5 mg, 0.16 mmol) in DCM (0.5 mL) was cooled to 0 °C. Allylbromide **357a** (17  $\mu$ L, 0.19 mmol) and DBU (48  $\mu$ L, 0.32 mmol) were added successively at 0 °C. The mixture was stirred at 0 °C for 10 min, then at r.t. for 7 h. DCM was evaporated and the crude reaction mixture was diluted in MeOH (1 mL), then cooled to 0 °C. An aqueous solution of KHF<sub>2</sub> **146** (37.5 mg in 0.5 mL) was added to the crude at 0 °C and the reaction mixture was stirred at r.t. overnight (18 h). The mixture was evaporated.
#### C.3. The ring closure metathesis (RCM) of hydroxamates 358a-c

#### Metathesis product 380.

Compound **358a** (170 mg, 0.43 mmol) and Grubbs catalyst  $2^{nd}$  generation 361 (18.1 mg, 0.021 mmol) were solubilised in dry DCM (13 mL) under inert atmosphere. The reaction mixture was stirred at 45 °C for 24 h. The reaction mixture was cooled to r.t. and H<sub>2</sub>O (5 mL) was added and the aqueous phase extracted with DCM (3 x). The organic phase was dried over MgSO<sub>4</sub>, filtered and evaporated. The crude product was purified by silica gel chromatography (eluent, hexane/AcOEt, 8/1, R<sub>f</sub> = 0.05) to afford **380** as a white solid (98.0 mg, 70%).

#### **M.p.** = 124 °C.

<sup>1</sup>**H NMR (400 MHz, Chloroform-***d***, δ ppm)** 7.42 – 7.29 (m, 5H, H<sub>11</sub>, H<sub>12</sub> and H<sub>13</sub>), 6.97 (d, J = 18.5 Hz, 1H, H<sub>4</sub>), 5.98 (bs, 1H, H<sub>6</sub>), 5.48 (d, J = 18.5 Hz, 1H, H<sub>3</sub>), 5.21 (s, 2H, H<sub>9</sub>), 4.53 (d, J = 2.7 Hz, 2H, H<sub>14</sub>), 4.31 (d, J = 2.1 Hz, 2H, H<sub>7</sub>), 1.27 (s, 12H, H<sub>1</sub>).

Reactions using **358b** and **358c** were performed using the same procedure as for **358a**. No products were isolated.

#### C.4. General procedure for the arylnitroso Diels-Alder/ring contraction sequence:

To a solution of **380** (1 eq) in a mixture of MeOH/DCM (6/1) was added arylnitroso compounds **160** (1.5 to 3 eq). The reaction mixture was stirred at the indicated temperature in the experimental procedure. The solvent was evaporated and the crude product was purified by silica gel chromatography.

Fused oxazine-pyrrole 386a.

Compound **380** (51.3 mg, 0.14 mmol) and nitrosobenzene **160a** (37.5 mg, 0.35 mmol) were stirred in DCM/MeOH (6/1) (2 mL) at r.t. for 24 h. The crude product was purified by silica gel chromatography (eluent, hexane/EtOAc, 6/1,  $R_f = 0.30$ ) to afford compound **386a** as an orange oil (39.0 mg, 96%).

<sup>1</sup>**H NMR (400 MHz, Chloroform-***d***, δ ppm**) 7.47 – 7.29 (m, 8H), 7.22 – 7.17 (m, 2H, H<sub>14</sub>), 6.87 (d, *J* = 2.9 Hz, 1H, H<sub>12</sub>), 6.19 (d, *J* = 2.9 Hz, 1H, H<sub>11</sub>), 5.26 (s, 2H, H<sub>5</sub>), 5.00 (s, 2H, H<sub>8</sub>), 4.76 (s, 2H, H<sub>7</sub>)

LRMS (ESI+) 307.0 (100%) [M+H]<sup>+</sup>.

**HRMS (ESI+)** calcd. for  $[M+H]^+(C_{23}H_{23}N_2O_5)$ : 707.1607 found: 407.1603.

Fused oxazine-pyrrole 386h.

Compound **380** (61.0 mg, 0.16 mmol) and 4-bromonitrosobenzene **160h** (45.9 mg, 0.25 mmol) were stirred in DCM/MeOH (6/1) (2.4 mL) at r.t. for 24 h. The crude product was purified by silica gel chromatography (eluent, hexane/EtOAc, 6/1,  $R_f = 0.35$ ) to afford compound **386h** as a yellow/orange solid (58.0 mg, 66%).

## **M.p.** = 92-95 °C

<sup>1</sup>**H NMR** (**400 MHz**, **Chloroform-***d*, **δ ppm**) 7.59 – 7.52 (m, 2H, H<sub>15</sub>), 7.44 – 7.31 (m, 5H, H<sub>1</sub>, H<sub>2</sub> and H<sub>3</sub>), 7.08 – 7.02 (m, 2H, H<sub>14</sub>), 6.82 (d,  $J_{6-5} = 2.9$  Hz, 1H, H<sub>12</sub>), 6.19 (d,  $J_{5-6} = 2.9$  Hz, 1H, H<sub>11</sub>), 5.25 (s, 2H, H<sub>5</sub>), 4.97 (s, 2H, H<sub>8</sub>), 4.74 (s, 2H, H<sub>7</sub>)

Polycylic product 390.

To a solution of **380** (50.0 mg, 0.14 mmol) [1 M] in acetone (140 µl), were added *N*-phenyl maleimide **2a** (25.7 mg, 0.15 mmol) and and 4-nitrobenzaldehyde **35** (42.8 mg, 0.28 mmol). The reaction mixture was stirred at 50 °C for 48 h. The solvent was evaporated and the crude product was purified by silica gel chromatography (eluent, hexane/EtOAc, 1/1,  $R_f = 0.50$ ) to afford compound **390** (28.1 mg, 38%).

#### **M.p.** = 79 - 81 °C

<sup>1</sup>**H** NMR (700 MHz, Chloroform-*d*, δ ppm) 7.44 – 7.29 (m, 8H, H<sub>Ar</sub>), 7.20 – 7.18 (m, 2H, H<sub>Ar</sub>), 6.05 (s, 1H, H<sub>11</sub>), 5.17 (s, 2H, H<sub>5</sub>), 4.47 (d, J = 14.2, Hz, 1H, H<sub>7</sub>), 4.45 (dd, J = 12.0, 7.1 Hz, 1H, H<sub>8</sub>), 4.36 (dd, J = 12.0, 8.8 Hz, 1H, H<sub>8</sub>), 4.21 (ddt, J = 15.7, 3.7, 1.9 Hz, 1H, H<sub>7</sub>), 3.58 (dd, J = 8.9, 5.3 Hz, 1H, H<sub>14</sub>), 3.35 (t, J = 8.9 Hz, 1H, H<sub>13</sub>), 2.90 (d, J = 8.9 Hz, 1H, H<sub>10</sub>), 1.92 (dt, J = 5.9, 2.8 Hz, 1H, H<sub>12</sub>), 1.30 (d, J = 2.1 Hz, 12H, H<sub>22</sub>).
