## Abstract

*Staphylococcus aureus* is an extra-ordinarily versatile pathogen causing a wide spectrum of infections. The aims of this study are to analyze 10 clinical isolates of *S. aureus* from the UK by Multi Locus Sequence Typing (MLST) and determining their PVL-type variants. In addition to that, to study the effect of several antibiotics at sub inhibitory concentrations on a number of virulence factors at mRNA using quantitative PCR and protein levels using proteomic methods. Western blotting was used to study differential expression of Spa at protein levels.

Data showed that the 10 clinical isolates belong to seven clonal complexes (CCs), which are CC1, CC5, CC8, CC22, CC30, CC88, and CC121. Genetic variation within *lukSF-PV* gene showed that three of these isolates were belong to the same PVL type variant of CA-MRSA USA300 strain, R variant. From which, two isolates were found to belong to the same CC of USA300, CC8. The remaining 7 isolates were found to belong to H variant. Data presented here showed that the sub-MIC levels of both cell wall inhibitors reduced *lukSF-PV* and *spa* steady-state mRNA levels when cells were grown in the presence of these antibiotics for one hour. However, after 5 hrs post antibiotic addition of these two antibiotics, vancomycin remained depressed *lukSF-PV* and *spa* steady-state mRNA levels as well as at protein levels, but oxacillin increased *spa* and *lukSF-PV* mRNA levels, as well as Spa at protein levels. Protein synthesis inhibitors clindamycin and linezolid were both caused an increase of *lukSF-PV* mRNA levels, but they both decreased *spa* mRNA levels, when cultures grown in the presence of these antibiotics for one hour. However, when cultures grown with these antibiotics for 5 hrs, clindamycin remained to increase *lukSF-PV* and decrease *spa* mRNA levels and protein levels, but linezolid decreased both virulence factors at mRNA and protein levels.

The data showed in this study confirmed that growing *S. aureus* in the presence of oxacillin induce toxin expression and might enhance the virulence of this bacterium, therefore using these antibiotics to treat *S. aureus* infections may contribute to worse outcomes. These data also confirmed that linezolid and vancomycin, are both important selections of antimicrobial agents to treat serious infections caused by the bacterium.

## **Acknowledgments**

I would like to say greatest thanks to my supervisor Dr Tony Fawcett for agreeing to accept me on to a Ph.D. place and for his continued help and support during my time on this project. At the Tyneside General District Hospital I wish to thank Dr Richard Ellis for his committed support and providing clinical isolates and Dr Angela Karnes from the Staphylococcal National Reference Laboratory in London for providing a number of clinical isolates for this study.

I am also thankful to Professor A. R. Slabas and Dr. Bill Simon for their help in use of the proteomic facilities, and in particular Joanne Robson for her long support and help in the proteomic part of this study and John Rowland for guidance in designing of the proteomic experiments and using the software for statistical analysis. I also would like to thank all members in lab 4 and 5 for their help throughout this study.

I wish to thank my colleagues and all members of the department of Biological and Biomedical Sciences for making my time enjoyable and for their willingness to help, and to DNA sequencing services, for their help in sequencing part of this study. I also wish to thank Dr Allan Seheult from Mathematical Sciences Department, Durham University for his kind help in Multidimensional analysis for some data.

Last, but certainly not least, I would like to thank my Mum, Dad and all loved ones for their continued support, particularly my wife Ahang because without her constant support this would not have been possible.

## *DEDICATION*

*This Thesis is Dedicated to My Wife Ahang, My Mum and Dad. It is Also Dedicated Proudly to My Uncle Abdul-Wahid and All Loved Ones.*
